WORKING CONDITIONS FOR FEMALE EMPLOYEES

MILTON H. KRONENBERG, M.D.

Chief, Division of Industrial Hygiene, Illinois Department of
Public Health
CHICAGO

The shift from peacetime to war production has increased the call for women, many whom have never worked before and others who have been engaged only in service, trade or other nonfactory jobs.

Considering the entire labor force of the United States, the employment of women has been increasing at a faster rate than that of men.¹ In March 1943 the number of women working outside their homes reached an all time peak of 15,200,000. Total male employment declined between March 1942 and March 1943 by 5 per cent, but employment of women went up 14 per cent.

In some key industries, such as aircraft, the number of women has risen from nearly zero to hundreds of thousands. In aircraft women total more than a third of the workers, in some individual plants more than half. In communications equipment 58 per cent of the workers are women, in scientific instruments 43 per cent, in ammunition plants 40 per cent, in electrical equipment 38.5 per cent and on down in varying smaller proportions in more than thirty separate important industrial categories.

Industrial management has approached the employment of women with not a little uneasiness. It is true that women have been employed for years on many light manufacturing operations, and they have excelled men in many jobs requiring patience and precision. But in those industries in which the employment of women has not been customary the change has involved a complete revision of many personnel and employment policies as well as extensive plant alterations.

The effective employment of women in industry depends in a large measure on thorough planning. This must be done well in advance of the employment of the first female production worker, for it is only through detailed planning that any program can be effectively initiated and maintained. Attention must be paid therefore to certain fundamental factors which serve as a guide for the utilization of these women on the production line in our war industries.

There are certain jobs and working conditions not suitable for women, but these are chiefly due to certain limitations of physique, biologic differences and experience.

It seems quite obvious that most of the precautions for health and safety recommended for women are equally desirable for men. Basically, poor working conditions and environments have no sex differential.

Nevertheless the employment of women calls for certain refinements of procedure that seem less important for men.

It may be said that any production program, whether in wartime or peacetime, can be attained and maintained over an extended period of time only when working conditions and unhealthful environments leading to fatigue, discomfort, ill health or accidents are eliminated as far as practicable.

In order to make the entry of women in factories as easy and successful as possible, recognition and consideration must be given to certain factors and requirements for their safe, healthful and efficient employment.

WOMEN AND MACHINES²

On the average, women are shorter, lighter in weight and not as strong as men. This statement is trite, and it seems needless to repeat it. However, it should be kept constantly in mind when reviewing any job where consideration has to be given to replacing men with women workers.

In most cases machines have been designed and fixtures developed for the reach, strength and stature of male operators. Most assembly jobs have been developed and time and motion studied with the reach, strength and stature of male workers as factors. Now female employees make it necessary to change machine design. Therefore the complete cycle of motions necessary to operate a machine or do a certain job should be studied so that the same amount of work may be done by women without an increase in personal fatigue.

This transition from men to women workers does not involve a complete redesign of machines, tools and equipment. It does, however, require a careful study of each individual job—preferably by a qualified time and motion study man or a combination of foreman, time and motion study man, and safety engineer and industrial physician—in order that all the elements may be given careful consideration.

In making such a study, the following changes should be considered:

1. Extension of levers on machines, tools and equipment in order to produce the same results with less effort.
2. Use of lighter weight and longer wrenches to reduce the strain on the operator.
3. Suspension and counterbalancing of heavy hand tools where substitution of lighter tools is not practical.
4. Lowering of work table, or raising of floor level, to compensate for the difference in the height of men and women operators.
5. Readjustment of machine guards because women's hands are smaller than men's.
6. Positioning of material so that it will:
 - (a) Reduce the number of body motions.
 - (b) Eliminate need for lifting heavy objects.
 - (c) Eliminate need for long reaching.

This paper, in a symposium on "Health of Women in Industry," is published under the auspices of the Section on Obstetrics and Gynecology.

SELECTION AND TRAINING

Experience has shown that the wholesale employment of women without some caution in selection will result in high labor turnover and absenteeism. Generally speaking, the selection and training of women is often more difficult and presents greater problems than those in the employment of men. Employment tests and procedures used in the past for the employment of men are not totally suitable for the employment of women. They must be altered to fit certain considerations. It is important as a first step in any selection procedure to know the type of work for which women are needed.³ Heavy or highly skilled work should be broken down into intermediate jobs wherever practicable. Jobs should be classified as to skill needed, health and safety hazards and physical strength required, so that personnel and medical directors may be in a better position to place the right type of woman employee in the proper job.

Women as a general rule, while lacking in mechanical experience, do not lack mechanical ability. Mechanical ability can be brought out only after proper training and experience. Initial training courses must be extremely elementary. Many women are entering factories for the first time and therefore will not be familiar with the common shop terms and tools. After careful training they can then be given more effective job training for their specific tasks.

What are the jobs in which women can be employed? This is a question, because women are daily going into jobs that never were previously performed by women. The only leading limitation appears to be the degree of physical effort required and possibly women's greater susceptibility to certain poisons such as benzene and lead. However, these factors can be controlled by early and adequate planning, such as the division and subdivision of jobs into several phases, by the use of mechanical lifting devices for reducing and eliminating physical effort and by adequate engineering and medical control for preventing and detecting occupational environmental exposures.

PROHIBITED EMPLOYMENT

Only a limited number of industrial employments are prohibited for women by legislation. Most of these prohibited employments are concentrated in the laws of a few states and many are prohibited or regulated in not more than one state.⁴ Many of the states have only a single prohibition or regulation. In twenty-two states and the District of Columbia there are no laws regarding the employment of women in any specific occupation. Federal legislation concerning the employment of women in manufacturing industries is chiefly contained in the Fair Labor Standards Act and the Walsh-Healy Public Contracts Act. All the federal and state laws should be studied carefully before placement and periodically thereafter for changes.

NIGHT WORK

It can be stated that night work is not beneficial to any one regardless of sex. The human mechanism is designed for and experienced in working by day and sleeping at night. Women appear to be more affected by night work than are men. Most employed women have responsibilities outside their hours at the

place of business, and, whether married or single, they bear some share in the care of the home. Outside of great emergency and absolute industrial necessity, night work for women should be restricted.⁵ Furthermore, make sure that the individual is able to work the night shift. No employee should be accepted if there is a history of anemia, digestive or respiratory disease or nervous disorder.

HOURS OF WORK AND FATIGUE

Experience gained during the last war is conclusive that long hours and fatigue impede production. The person handicapped by the physical poisons produced by fatigue cannot work so rapidly or so effectively as can the person who has sufficient time for rest and recreation. The matter of hours of work and fatigue is most important in connection with the utilization of woman labor. It can well be said that the success or failure of the movement depends to a great extent on what we do with reference to these things. The disabilities to which women are liable are readily caused or accentuated by irregular hours and habits. These conditions may become chronic and render the subject unable to continue her work or prejudice her future health. Fatiguing occupations and environments slow up the worker, increase the danger of accidents, induce various forms of nervous disorders and lower the resistance of the worker. If it is at all possible there should be transference of workers on monotonous processes to avoid fatigue. While there has been a striking trend toward the shortening of working hours and the lessening of fatiguing factors, under emergency powers those benefits and standards slowly achieved are often interrupted. In many states, to meet the war production demands, the need for longer hours is met by issuing emergency permits after a careful investigation that such a need exists.⁶ These have a limited time and are revocable.

Women are prohibited from working more than forty-eight hours per week in American industry. It seems that American management has felt that there is no need for longer hours and that above forty-eight hours neither the worker nor the management is benefited. The U. S. Women's Bureau has prepared recommendations in regard to the working time of women.

SEATING

Women should be seated at their work whenever practicable. However, neither continuous sitting nor standing is recommended, as both will produce fatigue. The work should be so laid out that the worker can perform her job either sitting or standing in order to allow some change in her working position from time to time. If practical, on highly repetitive and monotonous jobs the work should be so arranged that the operators must go after their work rather than have it brought to them. The seats should be of the posture type suitable for the type and nature of the work to be performed. Makeshift seat arrangements should be discouraged.

WEIGHT LIFTING

It has been recognized since women first worked that they should not be allowed to lift heavy loads or do work requiring great physical exertion if they are

3. Women's Role in War Production, Bulletin 4, U. S. Department of Labor, Women's Bureau, April 1942, vol. 9, No. 4.

4. State Labor Laws for Women, Bulletin 156, U. S. Department of Labor, Women's Bureau, 1938, pt. 1, summary.

5. Night Work for Women and Shift Rotation in War Plants, Special Bulletin 6, U. S. Department of Labor, Women's Bureau, June 1940.

6. Labor Standards for Women on War Work: The Woman Worker, U. S. Department of Labor, May 1942.

to be efficiently employed. There is a great variance of opinion relative to the safe maximum lifting load for women. State regulations are meager on this subject and in addition show great variance. In England it has been reported that women are allowed to lift a load equivalent to one-third their own weight.

The conditions under which the lifting is to be done must be known before any safe limit can be set. The chief factors to consider are:

- (a) The ratio of load to body weight.
- (b) The number of loads lifted.
- (c) The size and shape of the load.
- (d) Distance load is to be carried.
- (e) Period of sustaining lifting.
- (f) The levels of lifting.
- (g) Degree of rotation of the body.
- (h) Changes of level during carrying.
- (i) Method of lifting.
- (j) Physical condition and size of the woman.

The U. S. Women's Bureau⁷ has recommended that lifting loads be limited to 35 per cent of the body weight, however, this load appears to be excessive for a 90 to 100 pound girl. The best procedure to follow would be to prevent lifting wherever practical and to limit it to a minimum wherever it is necessary.

The safest method to employ regarding lifting would be as follows:

1. The plant physician should be made responsible for assigning any woman to a lifting job in excess of 25 pounds.

2. Every job requiring lifting should be carefully analyzed to provide and develop mechanical lifting and conveying measures such as hoists, cranes and tiering trucks. When lifting is necessary the work should be arranged so that the worker does not have to stack above her height.

3. Where lifting must be performed, the women should be properly instructed in lifting methods to avoid strain. For example, to avoid undue abdominal strain the feet should be kept close to the object and a narrow stance should be employed in which the feet are from 8 to 12 inches apart. A good procedure to follow is to bend the knees, keep the shoulders back and lift mainly with the leg muscles and not the back. Many back injuries are caused by lifting with the back.

4. Teach workers the safe and best way to carry weights. There are generally four methods for carrying loads. These are shoulder carriage, tray carriage, side carriage and hip carriage. This frees the lower limbs and does not result in fixation of the chest. This is particularly advantageous for the heavier loads that must be carried the longer distances.

Tray carriage (carrying in front) is at times best employed when carrying loads for short distances. However, fatigue of the arms and wrists is pronounced if this method is employed continuously.

Side carriage, that is carrying bundles at the sides, has the advantage of not disturbing body balance and not interfering with freedom of locomotion. However, the hands and arms also become decidedly fatigued if this method is employed for long continuous periods.

Hip carriage necessitates bending the body to the side to compensate for the lateral vector of the load. This carrying method interferes with normal walking and natural breathing. It is also tiring because of the rubbing of the hip and arm fatigue.

WORK CLOTHES AND PERSONAL PROTECTIVE EQUIPMENT

The longer women are employed the more it becomes apparent that work clothes should be provided for their safe employment. This should include suitable uniforms, caps, gloves and shoes. The type of clothing

to be provided depends on the type and nature of work to be performed.⁸ However, there are certain basic requirements of work clothes, for example:

1. The women should be consulted as to the type and design which they most like, and as to whether or not the proposed design is comfortable and practical.

2. The clothing should not be loose fitting enough to be caught in moving machinery.

3. The material should be attractive, durable and not readily inflammable, and it should launder easily. Bright colors have been reported as meeting with women's fancy.

4. The material should not collect dust and dirt easily.

5. Consideration should be given to the temperature of the workroom.

No wide skirts, loose sleeves, flowing ties or frills of any type should be allowed about any moving object. Slacks with tucked in blouses or coveralls have been found effective and can be made attractive. Neither slacks nor sleeves should have cuffs. Tight fitting work clothes may irritate, cause strain and result in fatigue. On the other hand, loose clothes may catch on protruding or moving equipment. Long sleeves rolled up are not desired, for the loose roll caught in a machine is more resistant to tearing when caught, and the result may be a serious injury. Outside pockets are not favored, but if necessary they can be a flat seamed or flat hip pocket.

If there is danger of fire, cotton material is preferable instead of rayon or other inflammable cellulose fabrics, for work clothes. Lightly starched fabrics are generally more fire resistant than those that have not been so treated.

Long hair is a most serious accident problem. Severe accidents have occurred about machines when hair has been caught in a moving part. Static electricity can draw hair into a moving machine despite guards. Therefore, caps with hair nets or tight fitting turbans should be worn. It is felt that a stiff hat (light of weight and fitting loosely) is preferable about moving machinery. This hat should be so designed that there is little danger of its being caught in the machine. In jobs where toxic dusts emanate, caps become of increased importance. In radium dial painting, for example, despite precautions, such as the handling of only a grain of powder at a time and mechanical ventilation, radioactive dust can be detected in the hair of dial painters with an ultraviolet lamp unless head coverings are worn.

Jewelry has no place in the factory. Many serious accidents have occurred from loose hanging jewelry. One does not need a vivid imagination to picture the horrible consequences of a necklace or bracelet being caught in a moving part of a machine. It has become a rule in many plants to prohibit the wearing of bracelets, earrings, large rings, wrist watches and all female decorative equipment.

Safety shoes are also important for the safe and efficient employment of women. Women should be required to wear low heeled, comfortable shoes. The high heel, toeless shoe should be prohibited. Not only do uncomfortable shoes cause undue fatigue, but they can also be a hazard. One of the commonest accidents among women is tripping and falling. In this source of accidents high heels, worn shoes, slippers or other improper footwear are major causative factors. In addition, open toe shoes should be prohibited. Closed

toe shoes prevent injuries from stubbed toes and the entrance of small particles of metal and other materials into the toes and the danger of toe infections. Safety shoes have not entirely met with the approval of women. However, where they have been made light and attractive, acceptance has been generally found.

SANITATION AND WELFARE MEASURES

Probably no single group of measures is more indicative of management's appreciation of the health, safety and comfort of its employees than the extent and adequacy of sanitation and welfare facilities. Employees react more favorably to these measures than to any other environmental change. Particularly is this more true of women than of men.

Much of the emotional adjustment of female employees can be aided by adequate and suitable sanitation and welfare measures, and the high labor turnover, which is evident during the first part of the employment period, can be reduced by such facilities. Few manufacturing plants had adequate facilities for women prior to the present war, and therefore the major physical or structure changes in the plant will probably be in providing these facilities. The extent and type of measures normally provided for men are generally inadequate for women.

There are many sources of information to assist in planning sanitation facilities for women. State and city health departments, the U. S. Public Health Service the U. S. Women's Bureau all have excellent literature on good sanitation practice. One of the best standards to follow is the "Safety Code for Industrial Sanitation in Manufacturing Establishments" of the American Standards Association.⁹ These standards are the most authoritative and were prepared in cooperation with the U. S. Public Health Service.

In providing toilet facilities for women the following are some of the minimum essentials:

1. It is necessary to provide separate toilets for men and women.
2. The U. S. Women's Bureau recommends that toilets for women be supplied in the ratio of one for each fifteen women.
3. Toilet rooms should be provided with adequate washing facilities and should be equipped with sanitary napkins and suitable dispensers.
4. Privacy demands that each toilet unit be enclosed and have a door provided with a fastener.
5. The minimum floor space allotted for toilet facilities should be 16 square feet for each toilet.
6. The construction and maintenance of toilet fixtures should comply with the state or city building and plumbing codes.
7. In the interest of sanitation, it is important that walls and floors of toilet rooms be of material as nearly as possible non-absorbent.

WASHING FACILITIES¹⁰

Women are most particular about skin hygiene, and therefore this fact should be considered in providing wash rooms. Managements that go beyond the minimum city or state requirements will find it well worth while. Wash rooms should be equipped with soap, hand lotions, skin creams in suitable dispensing units, individual towels, cleaning tissue and waste receptacles. Mirrors should be provided over a narrow glass shelf. The room should be well painted, illuminated, ventilated and heated. Good skin hygiene is a basic requirement for the prevention of dermatitis.

The following minimum practices should be instituted:

1. Washing facilities may be of the individual bowl, trough or wash fountain type. Troughs or wash fountains have the advantages of being economical to install and economical of space.
2. At least one wash basin with adequate water supply should be provided for every ten employees or portion thereof up to one hundred persons, and one wash basin for each additional fifteen workers or portion thereof. Twenty-four inches of sink with individual faucet may be considered equal to one basin. If the women are exposed to dermatitis producers, the ratio should be one wash basin for each five workers.
3. Showers may be necessary if women are placed on jobs in which the body becomes covered with grease, dust, grime and perspiration. If these are necessary they should be installed in the ratio of one per ten workers.

REST PERIODS

The benefits of rest periods have not been fully appreciated by many manufacturing establishments despite the fact that the introduction of such periods in England showed that in the majority of cases they led to an appreciable improvement in output, in spite of the loss of working time. It was found that a five to ten minute rest in the middle of the work spell increased output by 5 to 10 per cent.

Rest periods should be provided for all women workers, particularly those engaged in monotonous and repetitive work. The time allotted for such periods is best determined by individual plant study. The general tendency is to allow ten minutes in the mid-morning and midafternoon, although in some very monotonous jobs five minutes after each hour has been provided.

Rest periods should not be made to serve for all necessary health and safety measures. They cannot in themselves offset fatigue but are only one of the several measures for its control.

LUNCH ROOMS AND LUNCH PERIODS

Eating at work tables or in workrooms is a poor habit and should be discouraged. Not only is this practice poor hygiene, but, in the handling of toxic materials, a real danger of poisoning would exist from food contamination.

A separate lunch room should be provided, and provision should be made to supply hot lunches. Every effort should be made to educate women in good nutrition. The excessive use of carbonated beverages should be discouraged. Lunch rooms should be clean, attractive and comfortable. Facilities for obtaining and eating a good lunch in comfort will reduce absenteeism and also do much in the reduction of fatigue. A good industrial lunch room is another of the factors in attracting women to a plant and in maintaining a low labor turnover.

As important as a good lunch room is the provision of an adequate lunch period. The U. S. Women's Bureau¹¹ states briefly in regard to lunch period:

A lunch period is too short if it does not give the worker time to leave the workroom, wash and eat a well balanced lunch and have a few minutes for leisure afterward.

Workers handling harmful substances or exposed to harmful fumes or dusts should be given extra time before lunch for thorough washing. In some cases time for changing work clothes may be necessary to prevent serious cases of poisoning.

9. American Standards Association, 29 West 39th Street, New York.
10. Washing and Toilet Facilities for Women in Industry, Special Bulletin 4, U. S. Department of Labor, Women's Bureau, April 1942.

11. Women's Effective War Work Requires Time for Meals and Rest, Special Bulletin 5, U. S. Department of Labor, Women's Bureau, May 1942.

If the lunch room is inadequate to serve the expanding force with dispatch, or if it is distant from the workroom, additional time should be allowed, or provision made for carts with hot food to serve lunches at convenient points.

TRANSPORTATION

Transportation is also a matter of concern. Particularly is this problem important on the late afternoon and night shifts. Many women are afraid to leave or come to work at about midnight. In the case of young girls, parents may even prohibit them from work at this hour because of danger of molestation. Problems will likewise arise among those reporting for work at 7 a. m. or earlier.

No one solution can fit all transportation problems. Each is dependent on several factors, such as location of plant, type of transportation systems available and their schedules, and home location of employees. Some of the methods by which plants have met, or at least partially met, their transportation difficulties are:

1. Concentrated hiring from certain areas with special bus service to those areas.
2. Special bus service to and from main transportation terminals.
3. Employment on night and late afternoon shifts of those women with best transportation facilities.
4. Establishment of group riding.

HOUSING

As more and more women enter industry and particularly in large plants in rural areas, the housing problem will become acute.¹² It may be necessary in some areas to construct special dormitories for women. In any case the plant personnel departments should assist employees in securing satisfactory housing arrangements by securing a list of available rooms or apartments. In addition they should work with community agencies for housing and should stimulate plant executives to work with community officials in securing housing assistance from federal agencies.

Two of the first measures to meet the housing problems are to secure as much of the new personnel from present employee-families and to request present workers to provide housing for as many new workers as possible. Housing that is secured should be suitable and comfortable, for poor housing may develop many additional problems. All types of housing for women war workers should conform to standards essential for safety, security, health, decency, adequacy, privacy, cleanliness and comfort. Living quarters should be conveniently located in regard to workplaces and recreation facilities and be in pleasant surroundings.

NONOCCUPATION ILLNESS FACTORS

Illnesses of nonoccupational origin is by far the major type of sickness among any group of workers, and, in the case of women, this fact is even more striking.¹³ If efficient and continued production is to be obtained from women, it is these so-called nonoccupational diseases that must be vigorously attacked. It is in the control of these diseases that management will obtain the greatest economic benefits from its industrial health program. Therefore in the interest

of both management and labor, health programs must transcend occupational disease control and include a broad program of general health maintenance.

Present experience in England presents a warning to public and industrial health workers that must not be overlooked. This is the present sharp increase in tuberculosis, which has been especially large among women in general and particularly among young women. The cause for this increase in the tuberculosis rate is the most difficult health problem today confronting the health authorities in England. It is felt that overcrowding with increased contact, nutrition, worry and many other factors are all contributory, but as yet the one chief factor has defied recognition, as well as the reason for the predominance among young women. While it is not felt that the problems will approach the severity of those in England, we must nevertheless recognize all potential problems and guard against them.

There are certain factors and special physiologic conditions in the production of general illness among women which are of great importance in their efficient and healthful employment. These factors of general illness make the problem of good health maintenance greater in the case of women than in the case of men.

OCCUPATIONAL ILLNESS FACTORS

The true extent to which sex differences apply to occupational illness per se is not clear. Lead and benzene do appear to exert a greater influence on women, and women apparently are more susceptible to poisoning from these compounds. Dr. Alice Hamilton¹⁴ has stated that young women seem to be particularly susceptible to poisons affecting the nervous system. It has been generally felt that women are more susceptible than men to poisoning from trinitrotoluene, mercury, arsenic and carbon disulfide.¹⁵ This belief has not as yet been substantiated by sufficient clinical data. It has also been stated that lead and carbon tetrachloride are particularly dangerous to women during the antepartum and postpartum periods. However, there are many other materials, in fact, almost any industrial atmospheric contaminant that may exert an injurious effect on the blood forming organs, the liver or the kidneys which may be deleterious to women during these periods. It should be kept in mind that men also are adversely affected by the aforementioned materials. Simply prohibiting women from working with these materials will not solve the problem if men are similarly exposed. Every effort should be made to protect all workers from hazardous materials. If an environment is safe, it is equally safe for men and for women.

Dermatitis will in all probability become the major occupational disease among women during war periods especially in the early states of their employment.¹⁶ Women have always exerted great care of their skin. Rarely have they been exposed to the primary skin irritants which are found in industry. As a result of this skin care and lack of previous exposure the skin of women is generally more easily sensitized than that of men.

16. Carlisle, J. M.: The Health Problem of Women in Industry, in Proceedings of Seventh Annual Meeting of Industrial Hygiene Foundation of America, Inc., Pittsburgh, Nov. 11 and 12, 1942, pp. 170-175.

Care should be exercised in the placement of women, especially light skinned women, on jobs employing dermatitis producers. Many industrial maladies are the result of a specific exposure inherent in a certain process or operation. Dermatitis, on the other hand, occurs in many industries, operations and processes and may result from a great variety of manufacturing materials. The largest number of dermatitis cases in the past have resulted from the use of solvents. There are other occupational diseases which have occurred among women workers which are also prevalent among male workers. However, there is quite apt to be a greater frequency of these diseases among females as women become more deeply absorbed into our war production program.

Synovitis and neuritis of the hand, wrist and arm, and other diseases resulting from repetitive activity may become prevalent among women, owing to the wide use in industry of portable hand tools of the pneumatic and electrical types.¹⁷ This may represent a very important problem at present, for never before have portable hand tools achieved the wide use that they have today in industry.

Poisoning by lead and organic solvents must be rigidly guarded against during war periods. Because of the wide use of these materials, their high toxicity and of the displacement of men in the jobs employing these materials, they should receive added vigilance. During emergency periods, such as the present, there is a tendency to revert back to the more hazardous materials because of the fact that generally they do an excellent job, and the less toxic ones are more difficult to obtain. For example, benzene is now seeing wider use than previously because of the difficulty of obtaining toluene and xylene. War production requires great vigilance on the part of industrial health workers, for our production planners generally relax health precautions.

SAFETY FACTORS—ACCIDENTS

The accident problem associated with the employment of women in industry has received too little attention in the past. Statistics do not provide sufficient information. It does seem reasonable to state that, when women are carefully selected for employment, sufficiently trained in safety and for the job and not subjected to great physical exertion, their safety record should be as good as if not better than that of men, provided adequate machine guards and other safety measures are instituted. These guards and measures must be specific for women. Women are inherently more careful than men, and this should be of value in safety. Speed does not produce accidents but haste does; speed and safety can go together.

Accident statistics have shown that, in peacetime, accidents are fewer to women than to men. This does not prove that women are more safety conscious or that they have received better safety training but rather that women are not subjected to as many or as great accident hazards as men. However, even in peacetime there are a large number of accidents among women. The U. S. Women's Bureau¹⁸ made a detailed study of the accident reports of the states of Indiana and Pennsylvania, which contained 6,000 accidents that had occurred to women in one year. Injury to the upper

extremities were responsible for nearly two thirds of the Indiana accidents and a little more than one half of those in Pennsylvania. Machinery is probably the chief source of accidents to women. Those machines at which most of the accidents were found to occur were punch presses, power sewing machines, drill presses and cutting machines. All these machines can be equipped with proper guards which would have prevented any accidents.

Next to machines, falls are a major source of accidents to women. The U. S. Women's Bureau in analyzing the accident statistics of eight states found from well over one fifth to one third of all injuries to women were due to falls. It was also found that falls resulted in longer periods of disability than do other types of accidents to women.

How the changing occupational picture is affecting injuries to women is shown in recent Wisconsin figures. Reportable injuries to women increased from 147 in December 1941, or 5.8 per cent of all injury cases, to 209 in January 1942 and 240, or 9.2 per cent of the total, in March. As women constitute the largest group of inexperienced workers entering industry, great care must be exercised to insure their safe employment.¹⁹

It has been said that young girls have shown the higher frequency and the women over 40 the lower frequency. However, there is no definite proof of this as a general finding. In England, on the contrary, the older women present the higher accident rate.

One of the most striking features of America's economic development has been the increasing number of women income earners. During the last half century America has created many new kinds of jobs, and many of them have been for women. New inventions, mechanization of industry, the division and subdivision of labor tasks has made it possible for these women to enter the shop and factory. It is idle, indeed, to speak of the exclusion of women from the occupations. Women are in industry to stay.

1800 Fillmore Street.

ABSTRACT OF DISCUSSION

DR. JAMES M. CARLISLE, Rahway, N. J.: For the past year or more I have been carrying out the principles laid down in Dr. Kronenberg's paper, and labor turnover in our plant as well as absentee and accident records among women have been unexpectedly low. Women differ from men in their emotional makeup, and many women come into industrial plants who have never before worked outside the home or under any sort of discipline. They often bring with them numerous small cares pertaining to the home, as well as emotional upsets, which men are better trained to put aside while on the job. We have found the full time services of a woman's counselor helpful. Understanding feminine needs, she is often able to settle personal problems that might be obscure to the masculine mind but are nonetheless important to the worker's nervous equilibrium. Another factor that seems to help is having a woman doctor on the medical staff. Her presence is reassuring to women workers, who become less reluctant to report illnesses and accident or to undergo a physical examination. The maintenance of morale is of particular importance in keeping women on the job. Many who have come into war work on a wave of patriotism find the job losing its original glamor as time goes on and becoming mere drudgery. Then morale breaks down and various excuses are made for quitting. This is most likely to happen if the work is somewhat beyond the worker's strength and thus produces a sense of inadequacy or failure. For this reason I should like to stress the importance of job analysis.

which Dr. Kronenberg has already touched on. I refer to the analysis of a specific job with the object of breaking it down into operations that can easily be done by women and those that require a man's strength. This has been done successfully in our plant, with the result that the women suffer less fatigue and at the same time acquire a sense of proficiency and effectiveness. This appears to me to be one of the most important factors in securing maximum production from the woman worker and in keeping her on the job. We have not found women at our work stations in the manufacture of medicinal chemicals unduly susceptible to skin irritations. In spite of the greater area of skin usually exposed by women, our most severe and widespread cases continue to occur among men. It may be that our preventive measures together with the greater care women expend on cleaning and conditioning their skin is responsible for this favorable result. Back injuries have not been an outstanding problem, chiefly because men still are given most if not all of the heavy lifting jobs in our plant. Strains of the wrist and forearm, or tenosynovitis in that region have, however, been a fairly frequent disorder. These are not new, however, as they have been seen not infrequently in typists and clerks who do light but highly repetitive work with the hands. One type of exposure that women tolerate poorly is that of unpleasant odors. They complain of these much sooner than men do and are more frequently nauseated or made actually ill by them. For example, we have found it impossible to keep women at work on a process involving exposure to ethylene dichloride (dichlorethane). Dr. Kronenberg makes no mention of the strictly gynecologic and obstetric complications which may incapacitate women in industry. These have not proved as great a cause of inefficiency and absenteeism as we had at first feared, and it has been our observation that dysmenorrhea is less of a problem among those doing active physical work than it is in the sedentary clerical staff. Menopausal symptoms have been of minor consequence.

ANNA M. BAETJER, Sc.D., Baltimore: There is no evidence that either the physical or the chemical quality of the air, such as the temperature or humidity, toxic dusts, gases and fumes or the sanitary conditions of a plant affect the health or working efficiency of normal women differently from men. In spite of the statements in the literature that women are more susceptible to industrial toxic substances, there is no sound evidence at present to support this view except in cases of pregnancy. As Dr. Kronenberg has pointed out, "if an environment is safe it is equally safe for men and women" and vice versa. On the other hand, certain working conditions suitable for women differ from those for men, owing to several physiologic and social factors. First, since the physical size and strength of women are less than those of men, adjustments in machinery, in protective equipment and in the size and weight of loads are required. Second, because of the lack of experience and training of women in factory work, more care is necessary for the placement, training and supervision of women. Third, because of certain social and economic factors, such as household responsibilities and the care of children and the aged, women often work many hours each day outside the plant and may worry about these responsibilities while in the plant. These factors are largely responsible for the fatigue of women employees and are the principal reason why shorter hours, proper lunch and rest periods and less night work are desirable for women. Fourth, pregnancy and, to a much less extent, dysmenorrhea and menopausal changes make some adjustments in working conditions necessary. Pregnant women must be properly placed and supervised, and the working conditions must be arranged to prevent toxic exposures or fatigue. Lastly, although women have a lower mortality rate than men they have a higher morbidity rate, which manifests itself in industry by greater sick absenteeism for the common non-occupational diseases. The added home responsibilities carried by women probably contribute to this. Greater attention, therefore, must be paid to all factors in the conditions of work which tend to lower resistance to disease. The problems presented by the employment of women cannot be wholly solved by provision of optimum working conditions, but social, economic and other factors also must be considered.

HEALTH MAINTENANCE PROGRAM FOR WOMEN IN INDUSTRY

MAX R. BURNELL, M.D.

Medical Director, AC Spark Plug Division, General Motors Corporation
FLINT, MICH.

That the field of industrial medicine has become more and more that of preventive medicine is manifested by the reports of some of our largest industries. These reports show that year after year the amount of lost time due to occupational causes has become less and less, while that of nonoccupational illness and accident continues almost unabated. In fact, one large industry employing over 300,000 men and women reports that approximately 96 per cent of all lost time from illness and accident arose from nonoccupational sources. It is interesting to note that Lynch's¹ study of 16,648 cases of lost time from illness and accident resulted in almost identical statistics: "Sickness 86 per cent, non-occupational accidents 10 per cent, occupational accidents 4 per cent." He concludes that, if many of these lost man-hours are to be salvaged, the major problems concerned are not those of safety measures within the plant, important as those are.

With hundreds of thousands of women entering industry for the first time, this problem of public health reaches major importance when the future health of the nation is considered. It is well, then, to discuss the various relationships between the industrial physician, the private practitioner and local, state and national health agencies when any health maintenance program for women in industry is to be outlined, for it is a problem of public health in a greater measure than it is an industrial problem.

What part should the industrial medical department play in this consideration and why should health maintenance programs be given more emphasis than ever before, now that women have entered the front line trenches in the production of war materials? Selby² reports that "In a study covering 104 different industrial units in 36 states (1941) sick absenteeism rates for female employees averaged 320 per thousand per year with an average loss of forty-seven days. The male absenteeism rate was but 89 per thousand per year with an average loss of thirty-one days. Disability rates from respiratory infections are more than double those in males, as are those for digestive diseases. Nervous disturbances were six and a half times higher in women than in men. Pregnancy causes an absenteeism rate of 73 per thousand."

Gafaer,³ in a study covering a five year period, found that in disabilities lasting eight consecutive calendar days or longer the frequency rate was 68 per cent higher among female employees.

We may conclude that health maintenance programs for women in industry are important for the following reasons:

1. A much larger sick absenteeism is experienced among women workers.
2. Nutritional and digestive disturbances, loss of weight and so on are more frequently problems.

This paper, in a symposium on "Health of Women in Industry," is published under the auspices of the Section on Obstetrics and Gynecology.

been chosen from the nursing staff of the industrial medical department because of her intimate knowledge of the working environment of the plant and because of her ability to inspire the confidence of the distressed employee.

When the medical director or girls' counselor recognizes that the employee is suffering from frank psychosis or organic neurologic conditions, his duty is discharged when he has placed these employees in the hands of competent specialists in those fields. However, as Giberson⁸ has stated, "The source of most of the misery in industry results from psychoneurosis and frank maladjustments. The attitude of inferiority, chronic fault finding, overdependence, day dreaming, worrying, chronic nervousness and excessive fatigue are symptoms detrimental to business efficiency and human happiness. Maladjustments may be due to personality clashes, to family tensions, to malnutrition and to clearly recognized crises which appear in sequence in the life of the individual worker."

It is in this group that the work of the industrial physician and girls' counselor takes an important place in any health maintenance program.

Where large numbers of women are employed, the influence of the girls' counselor should be supplemented and a matron's service instituted. Carefully chosen older women are placed out in the factory where they are in constant contact with the employees. It becomes their duty to know every girl in their department. Each matron soon grows to be a recognized friend—some one to whom the women can talk. It is the matron who first notices early signs of anxiety, chronic nervousness, excessive fatigue or illness, and it is then her duty to refer the employee to the medical department, where she may be referred to the girls' counselor if the condition is one of maladjustment. Naturally this phase of health maintenance is not confined solely to the probationary period. However, it is during this formative period that the most benefit can be derived from such a function. The counselor and matron service has proved to be of far reaching benefit and a necessary component part of any medical department serving women in industry.

3. Recreation: That many of our women war workers are not using the hours away from work for diverting or restful recreation has given the industrial medical departments cause for considerable concern. Much short term sick absenteeism has been the result.

It is not the duty of the industrial physician always to suggest how these valuable hours should be spent, but it is his responsibility to investigate repeated absences and impress on the employee the necessity of restful recreation. The problem of excessive fatigue does not end at the factory gate.

II. CHECKING THE HEALTH OF THE ESTABLISHED EMPLOYEE

(a) *Establishment of the Individual Health Record.*—Johnson⁹ has brought to our notice the information that "12 to 15 per cent of employees cause 55 to 60 per cent of the time lost by sickness. This small group is sickness prone and should be the choice for concentrated attention along prevention lines."

Legge¹⁰ is of the opinion that "the plant dispensary is the ideal laboratory to study patients who seek advice for trivial complaints. This provides the opportunity to record and observe early symptoms, develop case reports, locate hazards and prevent morbidity."

The establishment of an individual health record draws the attention of the industrial physician to both of these groups. Further, health conditions in various departments of the plant may be compared and, finally, the overall problem of sick absenteeism may be intelligently studied.

(b) *Periodic Physical Examinations.*—The conducting of periodic physical examinations of those in apparent good health is such an established practice that little discussion of this phase of health maintenance needs elaboration. Early tuberculosis, pregnancy, circulatory and venereal diseases, diabetes and malnutrition are brought to light through this routine physical checkup.

In concentrating only on the "sickness prone" and the employee who seeks aid for "trivial complaints," it is well to remember that the apparently healthy employee may be developing a far more disabling disease.

(c) *Consultation Service.*—The medical director should set aside certain hours of the day to be devoted to consultations requested by the employee. The number of such requests will vary in direct proportion to the thoroughness of his health maintenance program and with the sincerity with which it is conducted.

This consultation service is especially important now that the problems women bring to industry are rapidly increasing. Dysmenorrhea, pregnancy and the menopause directly concern the industrial physician. In case of dysmenorrhea, he must decide how much pelvic congestion resulting from the employee's type of occupation influences her symptoms. Suitable wards where women may rest during this time are a part of the medical service and an important aspect in lessening lost time from this source. Further investigation as to the cause of the dysmenorrhea is the responsibility of the employee's own physician.

The menopause is another period in the life of the female employee that presents added problems. At no time in the industrial history of this country have there been so many women over 40 years of age gainfully employed. A condition with which the industrial physician rarely concerned himself now demands attention if he is to have a complete health maintenance program. It is not within his province to treat these employees medically—that is for the family physician—but transfer to lighter occupations requiring less nervous energy and concentration, along with sympathetic understanding, goes far in lessening disability during this trying period.

The consultation service is important in the case of pregnancy. The industrial physician should encourage the female employee to report to him as soon as she learns that she is pregnant. Thus he may advise transfer to lighter and less fatiguing work. His duty to this employee includes checking her environment to make sure there is no exposure to toxic substances. Further, he should see that she is receiving antepartum care by her own physician. If for any reason it is felt that this employee should not continue at work, the decision of the family physician should be final.

10. Legge, Robert T.: Bottlenecks and Progress in Industrial Medicine, *Indust. Med.* 11: 530 (Nov.) 1942.

To counsel women employees properly, the individual doctor should be familiar with the recommendations of the Report of the Committee on Health of Women in Industry of the American Medical Association¹¹ and the statements prepared by the Children's Bureau and the Women's Bureau of the U. S. Department of Labor.¹²

(d) *Health Education*.—The conventional approach to health education for employees is through the medium of posters, pamphlets, folders, articles in plant papers, speeches and motion pictures. By these methods the common cold, nutritional disturbances, tuberculosis, venereal diseases and the importance of proper care of the teeth may be brought to their attention. Such an educational approach should be made colorful and interesting. Posters designed by the U. S. Public Health Service act as an excellent example of this type of propaganda. Because many of these diseases are the greatest cause of disability among female workers, it is now more important than ever before that such an educational program be conducted.

(e) *Routine Factory Inspection*.—The routine inspection of conditions under which female employees are working is essential to good health. Of course the problems of ventilation and lighting are very much the same for male as well as female workers. However, the question of fatigue is one that requires much consideration, particularly now that many women are manning the machines formerly run by men. The adjustment of these conditions should not be left solely to the safety director, for only too often he does not appreciate the physiologic and structural differences between male and female workers. Furthermore, it is the responsibility of the medical director to know to what extent the female employee is subjected to toxic exposure. As mentioned previously, this is of vital importance in the case of the pregnant woman.

(f) *Health Conditions Outside the Factory*.—Knowledge of conditions in the community where the factory is located is an essential phase of a good health maintenance program. Frequent contacts should be made with the local health agencies so that the industrial physician may be prepared for epidemic keratoconjunctivitis, contagious diarrheas, tuberculosis, syphilis, gonorrhea, smallpox and poliomyelitis. The industrial physician often considers the health of the employees as something apart from that of the surrounding community. However, close cooperation with those charged with the responsibility of the problems of public health has proved most valuable to the industrial physician.

MEASURES EMPLOYED TO LESSEN LOST TIME ONCE SICKNESS APPEARS

(a) *Care of Minor Ailments*.—The recording of and caring for minor ailments is the best opportunity the industrial physician has to further "prevention." Abdominal distress, repeated colds and excessive menstrual periods are often found to be the early symptoms of gastric or duodenal ulcer, appendicitis, early tuberculosis or definite pathologic conditions in the pelvis. Emphasis on the advisability of a further examination by the patient's own physician sends many

to the doctor's office for relief of symptoms commonly considered too trivial to necessitate medical consultation.

(b) *First Aid in Urgent Illness Occurring While at Work*.—The giving of first aid to employees who become seriously ill while at work is the responsibility of the industrial medical department. Its duty is not discharged by seeing that the employee is returned to her home. She should be cared for in the industrial hospital until such time as the family physician can be notified and his advice followed. Length of disability from serious illness can be vastly lessened by seeing that prompt medical attention is obtained for the seriously ill employee.

(c) *Hospitalization Through Group Insurance*.—To protect employees adequately during illness, it has become increasingly evident that hospitalization should be provided through group insurance or some other plan.

Many industrial institutions have sponsored this arrangement. Such protection is especially needed at this time because of the overcrowded and inadequate housing conditions in many of our large industrial communities.

Proper nursing care shortens the period of disability. This is an important objective.

(d) *Visits to Disabled Employee by the Industrial Nurse*.—Management's interest in the disabled employee is made evident by the visits of the industrial nurse. The sick employee deeply appreciates sincere concern for her health. Confidence in the medical department is increased by sympathetic understanding and encouragement at such times. The duties of the industrial nurse include arrangement of sick benefit payments, allaying fear and apprehension on the part of the employee concerning her job, and other activities. It is a field of personal service.

(e) *Rehabilitation*.—The final chapter in the health maintenance program concerns the period of rehabilitation following serious illness or accident.

The employee should receive a careful physical examination at this time, and placement at work should depend on the findings of the industrial physician as well as on the opinion of the employee's own doctor that she is physically able to return to work.

The industrial physician is the one who best understands the worker's ability to do her usual work and advises that she be given less strenuous tasks or that she be allowed to work only part of the shift during this period of convalescence. He should be informed by the employee's physician as to the exact nature of the previous disability and value his opinion as to the present status of the employee's health. However, the final responsibility of safe placement at work must rest with the industrial physician.

CONCLUSION

To many this outline of a health maintenance program for women in industry may appear too detailed or wholly unnecessary. However, it is based on an experience in an industry that for many years has successfully employed thousands of women workers.

The ethical relationship between the private practitioner and the industrial physician, which has been discussed, should be reemphasized.

The success of any health maintenance program in industry depends on the extent of the "fact finding" of the industrial physician and the cooperation of the doc-

tor in private practice. That this can be done ethically and scientifically has been proved repeatedly. The best interests of the employee, the employer, the medical profession and the community are served when the responsibility of such a relationship is clearly understood.

ABSTRACT OF DISCUSSION

DR. LYDIA G. GIBERSON, New York: In the light of my own experience, the employment of matrons not specifically trained in social, nursing or psychiatric work might easily lead to a diffusion of effort and in extreme cases to the formation of shop cliques, which would defeat the purpose of the matron service. Wherever available help exists, the employment of a graduate nurse who is in the first place thoroughly familiar with the industry in which she is employed would be ideal and she should be given the additional training necessary to carry out the functions described by Dr. Burnell. Such a nurse should be of such a personality to invite confidence, and her patience and tact should be of high order. Fully recognizing the outstanding work many counselors have contributed, particularly during the war emergency, the soundness of some of the counseling services has often been impaired by a lack of specific training in recognizing emotional factors and their relationship to physical disease. My experience has shown that the creation of what may be termed a "zone of neutrality" by management has succeeded in gratifying measure in absorbing many of the frictional shocks arising from psychiatric or straight physical causes. The "zone of neutrality" is the psychiatrist's office where an employee may talk over his problems without any fear. The obvious conclusion is that there is a dearth of trained people, particularly as they relate to my branch of industrial medicine. It would be necessary that these be available before Dr. Burnell's well conceived program could be properly implemented. The only apparent answer for the moment is the additional training, at least in rudimentary fashion, of the already overburdened industrial medical personnel and the fundamental education of all persons coming into direct supervisory contact with the workers.

DR. H. A. VONACHEN, Peoria, Ill.: The attitude should change on certain jobs where the safety devices are based on man operation. One should regard women with consideration of the physical and emotional limitations of the sex, remembering that the female must be considered as three fourths of a man physically. I feel that each job should be studied from the standpoint of monotony, fatigue, lifting, lifting aids, lighting and rest periods. Perhaps the most important consideration is the physical examination (preemployment) with careful attention being paid to the all important previous medical history of the employee, particularly that portion which deals with female disorders and menstrual history. If the preemployment examination is thorough, at least 60 per cent of the potential industrial problems will be eliminated at the start. I feel that regular supervision allows early recognition of changes in the employee's attitude and application to work and reference of the troubled employee to the matron. We have instituted this system in the plant with which I am affiliated, with good results. Our policy with regard to pregnancy is explained to the prospective employee in a pamphlet given at the time of her induction. We cooperate with the family physician in this problem, the same as we do in all problems of the employee which are in the field of general medicine. It is our policy to refer immediately to the physician any case which we uncover and find to belong in the sphere of the family physician. In the case of pregnancy we require that the employee bring in a letter from her physician each month, keeping us informed as to the progress of her pregnancy. A leave of absence is arranged in the fifth month, carrying on until three months post partum, at which time she is returned to work if she can successfully pass another examination. We have an educational program pointed toward preventive medicine and personal hygiene which is carried on through the medium of the plant periodical, which is published biweekly and in which articles dealing with medical problems and diet are regularly presented in a section devoted to the medical division.

PROPER PLACEMENT OF WOMEN IN INDUSTRY

FRANK A. BARLOW, M.D.

Medical Director, Wright Aeronautical Corporation

PATERSON, N. J.

The entrance and acceptance of women in the heavier industries has been almost as spectacular and unexpected as the unsuspected attack on Pearl Harbor itself by the Nipponese. Little did we realize, at the start of all this, the important role women would occupy in the essential war industries.

Prior to this the operation of lathes, grinders, core-makers, molders and so forth was strictly a man's job. The mere thought or suggestion previous to the outbreak of hostilities with the Axis of women running the various heavy machines was pooh poohed and joked about. The majority of those in the heavy machine shops thought and said it could not be done. The emergency, however, became so great that something had to be done. Men were needed for our armies on all fronts—but they were also needed by our essential war industries. Military necessity demanded the release of manpower for the Army, Navy and the Marines. Production would have to be curtailed unless a worthy substitute could be found.

The problem of employing women to replace men on lathes and other heavier machines was started in the early part of 1942. The use of womanpower was not to create new jobs for them but to use their skill during the emergency. As a result of this newly created endeavor, many problems presented themselves both to industry and to society. Men were being replaced gradually by women between the ages of 18 and 60. The problems they presented were complex and difficult.

TRAINING PERIOD

The most obvious problem of all was the training of our newly acquired women employees. This of itself entailed many serious discussions between management and the government. The final outcome will probably come with the end of hostilities.

Before our industry could employ women, special permission had to be obtained from the Department of Labor. Our state laws pertaining to the employment of women definitely stated that they were not to work after 11:40 p. m., nor could they work more than forty hours per week. This law, of course, would have to be rescinded by the state department of labor in order to allow industry to employ women on the various shifts. As a rule the shifts usually are divided into three shifts per day consisting of eight working hours.

In addition to revising the labor laws, immediate plans had to be made to furnish proper rest rooms and toilet facilities as a necessary item to feminize the industrial world. Supervision had to be taught and educated in the proper handling of women workers. Women, as a rule, are very sensitive to harsh treatment. The old line foreman is definitely out of place in the modern plant.

A brief outline of our experience in training of female employees can be stated as follows (a word.

however, should be said here that our training program, since Pearl Harbor, has passed through many phases): A survey had to be conducted by plant management in the early months to determine the various jobs, in the many departments, that could be filled by women. It was concluded by the survey that hundreds of jobs could be done by our prospective female employees.

In order that the trainee might be properly fitted for her job, a training program as similar as possible to the working conditions of the plant itself had to be devised. Close cooperation between plant and the local vocational school was necessary. To facilitate matters further, identical machines were used at the vocational school as were used at the plant. Instructors were also furnished by the plant management. (The men picked as instructors were usually experts in their particular field. Although instructors in the vocational school, they were maintained on the payroll of the firm.)

The training period usually consisted of four to six weeks. At the completion of the training, the trainees were hired and placed on machines as operators.

Since the inception of these courses, the vocational school has become a unit of the defense training program—which is now known as the war production program—operating day and night to train qualified men and women to fill vacancies caused by plant expansion and loss to the armed forces.

The training of applicants depends a great deal on the type of work to be done by the individual. Of course, at all the training is done at the vocational schools: part of it is carried on at the plant itself.

In the early months of our program these trainees were not carried on the payroll, but as time went on the training program again changed, so much so that the following program is now in effect. It is the management's responsibility to induct new workers properly and to supervise adequately.

We now have two types of learners: student learners and regular learners. The student learner is hired and placed on the payroll but is not sent into the shop until she receives a thorough training in the particular job she is to accomplish when she has properly fulfilled the requirements at the vocational school. This type of learner spends eight hours a day for about four to six weeks or until she is judged capable. This type of worker is usually placed in the tool room or some special section in the assembly. The learner is then labeled as "specialized."

The regular student, however, is somewhat different. She is placed on the payroll and spends half her time in the plant and the other half at the vocational school. This program is in effect until her instructor and supervisor considers her eligible as a qualified operator. A few of the occupations taught at the plant itself, where women are now being used, are making cores, molding and even cleaning castings.

I quote our experience with the first 3 women employees hired for shop work:

1. A woman aged 20, single, who weighed 110 pounds (50 Kg.) and who was 5 feet 4 inches (163 cm.) in height, had formerly been a typist. As a learner coming from the vocational school she was given an opportunity to study and observe an internal sizeromatic grinder at work. When capable, she was transferred to a machine. She participated in the bonus plan and other plant activities. During the interval she was

allowed to run a machine and was shown her mistakes. She was treated on the same basis as a man. In two weeks' time she was operating an internal grinder exceptionally well. She was doing good work; the quantity of scrap was surprisingly low.

2. A single woman formerly a grammar school teacher qualified for the job of bench burrer in two weeks.

3. A woman aged 40, married, with three small children, sought a job at hole tapping to replace her 21 year old brother, called by the Selective Service. After two or three days she complained of her hand and arm aching. She continued working, but her efficiency dropped to a very low standard within three weeks. She was transferred to a sensitive drill press and within two weeks was excelling at the work. A woman aged 21, single, whose weight was 175 pounds (79 Kg.), was hired for the hole tapping job. She mastered the task in two days and is doing well.

CLASSIFICATION OF ENDOCRINE TYPES

From a theoretical point of view, women can perhaps be classified endocrinologically so that their behavior and physical and mental make-up can be explained on this basis, but from a practical standpoint of endocrinology one cannot properly place a female employee.

Women workers, as a rule, are subject to "nervous upsets." Few women have the physical strength that men do, probably because of the lack of rigorous physical training. Women workers do not have the same muscular strength as men. Muscular fatigue occurs more readily in women than in men. Thus, girls raised on the farms and accustomed to farm work have well developed musculature and are easily adjusted to hard laborious industrial work. For this reason a man with an average male musculature but with a slight heart murmur would be placed on a light job, whereas a woman with average female musculature and having the same heart murmur would be rejected for the same job. We believe the woman, with less physical reserve, would more quickly call on (and use up) her cardiac reserve than the man.

The glandular factor as it is reflected in women in industry presents some problems. Some glandular disorders have an obvious solution, as, for example, the pronounced hyperthyroid type, which can be corrected only by surgery. But the obese hyperthyroid and the menopausal woman present a problem of employment which is rather difficult to solve and which probably can be only completely solved when we have given these women a thorough trial in industry.

The average industrial interviewer when choosing a woman to do somewhat heavier work is often misled into selecting the heavier woman, confusing fat for musculature and strength. Actually the stout woman has little advantage over the lighter woman in the heavier industrial work except in certain situations where she can use her weight, as in pushing a food truck. In general, an obese woman has less stamina and less physical reserve and is more apt to succumb to various disorders because of her weight, varying all the way from varicose veins to cardiac decompensation.

The menopausal woman presents a tremendous problem, which can be divided into three major factors: (1) obesity, just described, (2) nervous and psychiatric disorders, and (3) hypertension. Of course there are many other factors, including the industrially impossible female who combines all the major factors

of the menopause—the obese, the psychiatric and the hypertensive woman.

All the psychiatric and nervous women should be examined, prior to employment, by a qualified psychiatrist. This, however, is most essential where women applicants predominate. His is the problem whether or not the applicant is stable enough for an industrial position.

The hypertensive case can be classified according to arbitrary standards. These standards vary of course with the needs of industry. In times like these, where manpower is at its low ebb, standards must be forgotten. I remember, prior to our entrance into the war, where an applicant (male or female) was rejected with a systolic pressure range above 150 mm. of mercury and a diastolic above 90 mm. of mercury. As a maximum passing requirement, at the present time, a systolic pressure range of 200 mm. of mercury and a diastolic of 100 mm. of mercury is acceptable, although we try to place these persons in light or very light occupations.

It would be ideal to go into elaborate studies and determine the origin and type of hypertension, but this is not practical in large scale hiring. Only with the passage of time would we be able to determine how successful we had been in our selective process by determining statistically what percentage of applicants can maintain the position to which they have been assigned. If the percentage is extremely low it will mean that we have been too lenient in our selection, but if the percentage is extremely high it implies that we have been too rigid in our selection and have probably deprived war industries of some useful employees.

PREEMPLOYMENT PHYSICAL EXAMINATION

A thorough preemployment physical examination is just as applicable to women as it is to men. As a matter of fact, the problems differ as to both sexes.

Women bring certain problems to industry, and these problems are, medically, mainly due to their difference in physiology—to the fact that women bear children and men do not. Thus, they present the additional problems of menstruation, the menopause, pregnancy and the care of children. This should be a nucleus for the examining physician to bear in mind in the examining of all female employees.

It must be borne in mind that women are more apprehensive than men. To many of these women the thoughts of a complete examination frightens them. Frequently they have never worked outside their own home or may have come from jobs where no physical examination was required. Then too the thought of being examined by a male physician makes many women, if not all, rather apprehensive. She is willing to go to her own physician, or any other physician of her choice, when she is sick or thinks something is the matter with her. She is willing to be thoroughly examined and submit to various tests to get rid of her ailments. In an industrial plant neither of these factors applies, and most women feel most apprehensive.

As industrial physicians we want to give the employee as thorough an examination as possible both for her own sake and for the sake of her fellow employees but still have it pleasant and free from any embarrassment. We want her to realize that the examination is for her benefit as well as for the particular industry she is to enter. These factors sometimes play such a part as

to influence and make it difficult to interpret properly the resulting examination. This particularly is true for the average industrial physician who himself is a newcomer to an entirely different field.

Women, as a rule, are usually less nervous when they know they are going to be examined by a woman physician. Thus, a woman physician can do a more thorough examination, particularly as regards hernias, pregnancy, cystoceles and rectoceles, without embarrassment on the part of the woman applicant.

A complete pelvic examination is not done at any of our preemployment examinations. If a thorough examination is necessary and essential from preliminary workup, she is referred to her family physician for this pelvic checkup.

The physical examination, to be of any benefit, should be as thorough as possible and should include a brief personal history. The examiner must know the type of work to be performed by the employee. One should observe the general appearance of the applicant, check for varicose veins, note all deformities, examine for hernias, both femoral and inguinal, and note the condition of the applicant's spine, skin, kidneys, blood pressure and vision. X-ray examinations, a Wassermann test and urinalysis should be included.

The physical requirements will change from time to time, depending on the type of work and also on the type of industry. I remember, not too long ago, when prospective employees had to be practically perfect before they were passed physically for employment. Today this does not hold. Owing to the shortage of manpower we had to lower our standards and we are still lowering them.

One must bear in mind that it is only by a proper and thorough physical examination that we can properly place our prospective employees. The applicants of today have been sifted over and over rather thoroughly, and what remains to be hired is not a very select group, physically speaking. The incidence of major defects in this group runs high. Before the war, applicants with major defects were not hired; but now we must try to place as many applicants as we can, despite their large handicap, in occupations where they can do no harm to themselves.

These handicapped employees should be encouraged to recognize their responsibilities as permanent employees alongside those who are better endowed physically. This applies only to those physical handicaps which are not objectionable or dangerous to fellow employees. Diseased persons should not be accepted into industry. A problem recently came to my attention of a young woman who was passed by the examining physician. A notation was made on her chart of a dermatitis of both hands of a noncontagious or non-infectious nature. She in turn was accepted by the interviewer and supervisor, who were told of the skin rash. It was not too many hours after starting that her fellow employees started to grumble and become dissatisfied because of her skin condition. It became obnoxious to them and they threatened to leave their machines unless the woman was removed. This happened not once but four times in various departments until we had to ask the girl to leave her job temporarily—at least until she had the rash on her hands cleared up completely.

Another condition which is frequently missed and difficult to diagnose in the female applicant, unless otherwise obvious, is an inguinal hernia. We have seen four inguinal hernias in the past six months. Prior to this I had not seen one single inguinal hernia in the past eleven years. These hernias, if they had existed before employment, were completely missed. In the first instance a girl aged 18 years was employed only three weeks when she came to the hospital complaining of pain and a lump in her right side. Two other women were in their late twenties and were employed only two to four weeks. The fourth was a girl in her late teens and was employed only one week.

I do not believe that women who are pregnant should seek employment, especially in the heavier industries. Of course, if they are already employed, certain allowances should be made. The matter of time is an arbitrary one, depending on the length of time employed, her physical and mental attitude, previous pregnancies and finally the danger to which she is exposed. Epileptic women, however, should not be accepted under any circumstances on machines either light or heavy. They can nevertheless be employed on light inspection work away from all machines and on clerical jobs.

Women, as stated before, were placed almost exclusively on clerical work, but now they are placed in the shop. Among the machines which women are operating efficiently are milling machines, turret lathes, tapping and drilling machines (including large multiple spindle drills), punch presses, grinders of many types, including internal and external cylindric, thread, centerless and surface, as well as cutters and other tool grinders. They are also becoming proficient in the foundry as coremakers, molders and casting cleaners.

FOLLOW-UP

The follow-up system used by various industries is a valuable adjunct in evaluation and proper selection of the new applicants. It is true that, no matter how perfect we think our selection of female factory workers may be, they nevertheless require continuous follow-up to determine whether or not the new applicant is mentally and physically satisfied with her newly assigned job and also with her new environment. It must be remembered that only a few of the women had any shop experience before taking on their present jobs. All the women employed had to learn the jobs they now perform, but they are doing them as well as male employees, whom they now outnumber about three to one.

Here in our plant all follow-up of new employees was previously done by male clerks from the personnel department. They interviewed male and female employees, but as time went on it was decided to use women in the follow-up of women. This job was then designated to the female counselor. It is the function of these counselors to become thoroughly acquainted with all the help allotted for the overseer. The first interview with the female employee takes place about the fifth or sixth day after she has been hired. This interview usually takes place in the department. This is often spoken of as the "first contact." The employee is approached for the purpose of getting acquainted. It is strictly intended as a friendly chat, having both parties discuss what is uppermost in their minds. The

discussion will, of course, vary with the individual. Some will discuss the type of work which is assigned, while others will want to know about insurance, health, sickness and occasionally home affairs. These interviews, as a rule, lead to a better understanding and better cooperation between supervisor and employee. Usually, health problems which were merely mentioned to the examining physician are more thoroughly discussed and explained.

The second interview, which is really considered the follow-up, takes place five or six weeks after hiring. The discussions here usually tie up with the first interview, only on a larger scale. By this time both employee and counselor have become acquainted and a closer relationship thereby exists. In our plant, care is exercised by our counselors never to divulge any personal confidences or expose the employee to supervisor, management or any other plant agency. Everything is held in strict confidence. It should be stated here, however, that supervisors were rather slow to get adjusted to these new developments. But at the present time they have realized the value and necessity of this service and they are more cooperative. I understand that at times this second interview is almost entirely medical. It seems that women are much happier and contented when they can find a welcome ear to tell their troubles to. In addition, we find that they discuss rather freely their emotional status and their special female functions of the menopause, menstruation, pregnancy and dysmenorrhea. Also isolated cases are brought to light in which help can be given with later transfer to a more suitable occupation. As an example I will briefly cite a case which was brought to my attention by one of the counselors:

Mrs. H. L. received some radium burns about several of her fingers while in the employ of a research medical laboratory during the first world war. The burns were only minor and completely passed both the examining physician for the company and the examining officer of the Navy. She was assigned to a bench burring job. This in turn required her to use emery paper for buffing and polishing. This caused an irritation and aggravation of the radium burns about the fingers. She was reluctant to mention anything about this to her foreman for fear of losing her job, but she did mention it to her counselor, who in turn, with the permission of the woman, reported the incident to the medical department, which in turn recommended an immediate transfer to another job that required little use of the fingers. This recommendation was acted on, which was most satisfactory to the employee.

The third and final interviews take place about five to six months later.

CONCLUSION

The important thing to keep in mind now is that women are on the job in war industries. They are turning out the quantity and quality of work the war demands.

The majority of our women are successful at small precision machine work and are more attentive to a repetitive job than men. Generally speaking, women are not as inventive as men. If a machine should break down nothing is done about it, whereas a man will make every effort to find out what is wrong and then make arrangements for the proper repair.

Our nation will need the particular strength and ability of women even more as time goes by. It is

only sound sense to do everything possible, within the plant and beyond it, to safeguard their health and efficiency for ultimate victory. Total war is a new game for Americans, but I am positive that we have the ability to utilize all our resources effectively.

ABSTRACT OF DISCUSSION

DR. W. A. SAWYER, New York: Most industries are employing a great many persons with major impairments. This is not too serious, provided there is careful job placement. If jobs are studied from the point of view of what a woman can do and the work is reorganized mechanically, as it has to be in some instances to fit the woman's physical capacity, the end results are generally satisfactory. We are all amazed at the variety of jobs which women can perform. More attention must be paid to a woman's outside activities and responsibilities than ever has been paid to a man's. Even if a woman does not have a home with children to look after, which gives her two jobs instead of one, there are many things which she has to do for herself and which, with a long work week, she can do only if she takes time off. That in part accounts for the high rate of absenteeism. Woman's place in the community in some respects requires more of her than it does of a man. Industry will have to adjust its schedules and hours of work to enable women to do two jobs. If the strain of doing two jobs becomes too great or if the woman is not sufficiently strong physically and well enough integrated mentally, sooner or later she will become fatigued and possibly seriously ill. I do not believe that a woman trying to carry a double load can last much more than a year without exhausting herself. No woman who is conscientious about her home and children is going to be able to work as wholeheartedly at her job when she knows that the home and family are suffering as a result. In my own community there are far too few agencies and facilities to care for children during working hours. If this war is to go on for a number of years, certainly this phase of the problem must be developed more adequately. Recently the question arose of changing to the night shift a woman weighing 106 pounds who had two small children. She lost her husband in North Africa a year ago. Her mother is taking care of the children during the day, but she does it unwillingly and not too well. When the question of changing to the night shift came up this worker rebelled, and rightly so. If she should go on night work there would surely be a breakdown. One could cite cases of this type again and again. There is no problem of training women to do the work they are wanted to do. Allowances have, of course, been made for them physically, and the absence rate is high. The question of pregnant women has not been a troublesome one. The great problems have been nervous exhaustion and the usual run of other illnesses which, I believe, are due in large measure to the strain of trying to do two jobs.

JENNIE MOHR, Associate Industrial Economist, Women's Bureau, U. S. Department of Labor, Washington, D. C.: Despite the shortage of manpower, it seems rather extreme to say, as Dr. Barlow does, that "standards must be forgotten." Even if workers are scarce, it does not pay to take on those incapable of working or incapable of sustained production. Standards need not be forgotten, but they must be realistic. That means that the factors discussed by Dr. Barlow should be part of a placement program for each individual worker and that workers be utilized to their fullest capacities, but not beyond. There seems to be some difference of opinion among physicians as to the extent to which the menopause is a serious deterrent to the placement of older women. Dr. Barlow calls it "a tremendous problem." Other physicians have said that, unless some specific abnormal condition appears, industrial life seems to offer no greater obstacle to older women than do other circumstances. It is true that older women have not been used in certain industries to the extent to which they are now being used. In others, such as the manufacture of clothing and textiles, older women have long been employed as a matter of course. In any case, as

Dr. Barlow indicates, their placement on jobs must be the result of a careful analysis of their physical and psychological abilities. A well defined plant policy concerning the employment of pregnant women is an essential part of a placement program. The fear of being fired as soon as they are known to be pregnant leads women to conceal their pregnancy and makes impossible their protection against work or working conditions that may be especially dangerous for them. With respect to laws regulating the employment of women, it should be noted that the forty hour regulation to which Dr. Barlow refers pertains only to the payment of overtime beyond that number of hours and applies equally to men and to women. Laws regulating the hours women may work vary from state to state. In the state in which Dr. Barlow's plant is situated, women may work fifty-four hours a week. One must not forget that women are not new to industry, not even to heavy industry; they are new only to some plants. During the first world war women operated many machines, such as turret and bench lathes, punch and drill presses, millers and grinders, and took on many new jobs under the pressure of war. In 1930 there were more than 60,000 women operatives in iron and steel, machinery and vehicle industries, 3,000 of them in blast furnaces and steel rolling mills. Our present concern is to see that now, and continuing after the war, the placement of women in jobs is done with full consideration of all we can learn about their needs, limitations and capacities. To this end it would be of the utmost value if physicians would undertake studies to determine the specific effects on women of certain occupations or certain working conditions about which we can at present only speculate.

DR. GEORGE MORRIS PIERSON, Philadelphia: In addition to the points brought out by Dr. Barlow there are many other problems of far reaching importance that must be considered in connection with the placement of women in industrial jobs. It has long been recognized that women should not be required to do heavy lifting. Efforts to regulate this has been attempted, but no satisfactory formula has yet been devised. The safest rule is to limit all lifting to a minimum and to avoid it whenever possible. The role of fatigue takes on added importance in the case of women employees. It has long been recognized that fatigue is one of the chief factors responsible for reduced production, accident frequency and sickness absenteeism. Since it is admitted that on the whole women are more susceptible to fatigue than are men, special efforts should be put forth by employers to control the fatigue factor in the women employees. The length of the work week has been shown to be one of the most important influences in the production of fatigue. An example of this was found in England; when the work week was increased to seventy-five hours women suffered 287 per cent more accidents, an increase over twice as great as that observed in men under similar conditions. The total work accomplished in a given period of time is definitely increased by regular periods of rest. Closely allied to this phase of the subject is the question of night work. It is generally conceded that the physical effects of night work are much more disastrous to women than to men and that such deterioration occurs sooner in women. In order to minimize accident hazards, women who are employed, especially in those industries in which complicated machinery is used, should abandon their ordinary attire for suitable work clothes. They should be required to wear overalls, suitable low heeled, closed toed shoes, gloves whenever rough or irritating materials are to be handled, and the hair, particularly if it is long, should be adequately protected. The introduction of women into industry has focused renewed attention on the importance of providing good working conditions and making available clean, comfortable and cheerful rest rooms, wash rooms and eating facilities. The often discussed and important problems connected with menstruation, pregnancy and the menopause in women workers need no further elaboration. Even with the successful conclusion of the war it is not unlikely that many women now employed will continue to be actively engaged in various industries. The questions that arise in connection with their proper care are therefore not merely ones for immediate concern but will engage the consideration of employers and industrial physicians in the future as well.

SPECIFIC PROBLEMS OF WOMEN
IN INDUSTRY

H. CLOSE HESSEL TINE, M.D.
CHICAGO

From the obstetrician's and gynecologist's point of view specific problems of women in industry should include menstrual disturbances or abnormalities, the menopausal syndrome and pregnancy. Gonorrhea and the other venereal diseases with the exception of syphilis have as yet no established relationship to absenteeism. Even though syphilis is a serious complication in obstetrics and gynecology, the dermatologists and syphilologists have exhibited special interest in its relation to employment. Nutritional needs and food shortage loom larger as the complexities of food ration and the point system extend particularly for wives and still more so for mothers who have limited time for shopping and preparation of meals because of their employment. Other important considerations are the preemployment examination and placement, health maintenance programs and working conditions of women employees. By assignment, this elaboration will be restricted to menstrual disturbances, menopausal symptoms and pregnancy in relation to employment.

The term woman or women will mean all females of the age of 15 years and over, unless specifically indicated. In a strict sense the biologic and physiologic age should be employed, but because of its variability in relation to the definite chronological age and because a mean average is adequate the arbitrary selection of 15 years and over has been rather generally accepted. Objections to the employment of these really young women has come forth, but the extreme labor shortage and the great urgency for employees have caused a relaxation of the rules governing employment and necessitate a survey of the whole problem. Women may be divided readily into two groups: (1) menacmic, or 15 to 44 years inclusive, and (2) postmenacmic, or 45 years and over. Again, this is an arbitrary division but it will serve the purpose.

The need for women in almost all industries has reached the greatest peak for percentage employment. It is common knowledge that women have recently, for the first time, entered into types of work which heretofore was performed exclusively by men. Many industries encountered new and troublesome problems with the admission of women employees, while those plants accustomed to female workers experienced little difficulty as a rule. Even plants experienced in the problems peculiar to women faced new problems through the use of women who were unaccustomed to employment. In many instances new policies, as well as the increased number of women, favored difficulties.

In normalcy those who could not or should not work regularly and dependably could be replaced. Also in normalcy the placement of the employee was easier because of much lower turnover rate and because of regularity in replacement. The total number of employed women continues to grow, and the choice of acceptable employees becomes less and less favorable from a medical point of view.

Because reliable information is not available, it has been necessary to utilize opinions and ideas to formulate even a preliminary program for the conditions peculiar to women in relation to their employment. However, certain facts are available on the female population, and these permit some calculation.

FEMALE POPULATION AND LABOR FORCE

It has been estimated that 18 million women will be needed and probably obtained for employment by December 1943. Table 1 indicates the trend since June 1940. For May 1943 there were about 400,000 women desiring employment, while about 15,900,000 were employed, which makes a total labor force of 16,300,000. The great number now working and subsequently needed in nonagricultural positions must be secured from urban areas (generally communities of 2,500 and more). This means that about 1,700,000 more female workers must be procured from an essentially empty reservoir to fulfil the estimated quota for December 1943.

45 years and over.....	3.3	3.4	10.7	17.3
15 years and over.....	9.6	9.6	30.2	49.4

June 1943 estimates would not exceed 2 per cent probably that of April 1940

Table 2 gives the distribution by community and menacmic status. On calculation of present day population of women it seems definite that the number would not amount to 51 million. Of this number nearly 60 per cent are in urban communities. Approximately 66 per cent of the urban group are under the age of 45.

A further restriction to the theoretical calculation of available women is the number of mothers with small children (table 3). Recently it was reported that about 7 million women have children under the age of 5 years and 11 million have children under the age of 9 years. At the present time it is very probable that about 3 million women have children less than 1 year of age. These data illustrate some of the conflicting views relative to an available labor force. Another factor is the demand in individual communities which is out of proportion often to the available help. This applies to concentrated industrial areas and to small urban communities where special projects have absorbed all the available laborers and need more. Industries competing with one another have caused much disturbance in production through a rapid turn-

This paper, in a symposium on "Health of Women in Industry," is published under the auspices of the Section on Obstetrics and Gynecology.

over of employees. This great change has taxed the plant physician, who must examine each employee whether the employee remains or leaves within a short period.

The use of women in all and in war industries is concretely expressed in table 4. In December 1942

TABLE 3.—*Estimated Number of Women with Children, April 1942**

Expressed in Approximate Millions

there were approximately 15 million in all industries, which was about 30 per cent of all women. About 3 million were employed exclusively in war industries. This represents about 7 per cent of all women, or 23 per cent of the employed women. The projected figures for December 1943 are 18 million in employment, or 36 per cent of all women of 15 years and over. From this group some 6½ to 8 million women, or 13 to 16 per cent of all women or 36 to 44 per cent of women employees will be utilized in war industries alone.

The labor shortage is so acute in some localities that some plants would have to employ many who could not pass the satisfactory preemployment physical examination if 100 per cent quota of employment was to be accomplished. Table 5 lists the types of female employment as of May 1942. The great scarcity of present day domestic and personnel help illustrates that the great bulk of this group have already shifted into other types of work or retired from work. It seems certain that many from other groups have gone also to the war industries. It is rumored that some professionally trained women, as nurses, have given up their profession to go directly into ordinary employment because of better pay of the latter. This type of shift is a distinctly unpatriotic act at a time when skilled and experienced people are in such great need.

† Women's Bureau Release "Women in the Labor Force," July 18, 1942.

‡ Author's estimate.

Arguments continue on the relative merits of essential work in amusement and recreation.

Various answers and proposals remain before us for meeting the labor shortage and production demands. The solution appears to be the elimination or reduction of each of the causative factors. Lynch¹ observed that 6.3 per cent of all sickness disability of eight or more days duration resulted from genitourinary con-

ditions. Mothers or wives may elect to absent themselves to perform household duties, such as laundering, shopping or caring for a sick member of the family. These mothers and wives often work almost as many hours at home as at the plant, which predisposes to absenteeism. Others may remain away from work for personal and nonvalid reasons.

An evaluation of women not in the labor forces indicates that sacrifices must be made by many of these if they are to become employees. Likewise, absenteeism may be increased in this group. Table 6 shows the relation of the unemployed female of the age of 14 years and over to their class. In April 1943 there were approximately 36,200,000 females not working. Slightly under 30 million (29,400,000) were doing their own home and house work, while slightly over 4 million (4,200,000) were in school. From these and other figures it is evident that, if the increase in the labor force is to continue as planned, more wives and more mothers must enter industry.

The Labor Force Bulletin, L. F. B. No. 3, June 17, 1943.

WOMEN EMPLOYEES AND PRIVATE PHYSICIANS

The ratio of physicians to the public and the employed woman has changed greatly. The armed forces have and will continue to take many physicians. At present there are about 88,000 active physicians for the civilian populace, which makes a ratio of 1 physician to slightly over 1,400 people. By December 1943 the ratio will likely be 1 active physician to each 1,500 civilians. This will make a mean average of 1 active physician to slightly over 200 employed women. Obviously these averages do not reveal the deviations which occur in various communities. These facts reveal that every physician should become even more interested in the problems of women as related to their employment. This education on the part of the physician is essential for better cooperation with the plant physician in the interest of employees and the physician's patient. The better the cooperation, the more conducive it is to the war effort. Previously, industrial physicians were not particularly concerned with obstetric and gynecologic conditions, for such states fell in the category of nonindustrial conditions. Nowadays the industrial physicians face greater burdens through new problems in connection with all new workers, many of whom are unskilled, unprepared and unaware of dangers or

1. Lynch, D. L.: Industrial Health and the War, New England J. Med. 227: 209 (July 30) 1942.

safety precautions. Industrial physicians will welcome the opportunity of reciprocation in appropriate cooperation with the obstetrician and gynecologist.

MEDICAL PROBLEMS

The Committee on the Health of Women in Industry of the Section on Obstetrics and Gynecology of the American Medical Association² made recommendations pertinent to the essentials of a medical service in industry, general hygiene for women in industry, need for physical examinations and placement and the states of menstrual abnormalities, of the menopause and of pregnancy. It has been insisted³ that the future programs and policies will have no better foundation than the present unless exact information is obtained about these specific problems of women in industry.

Adequate data on absenteeism from menstrual irregularities and distress, the menopausal syndrome and pregnancy are not available. Progress is obstructed badly through the lack of specific data. Such data could be accumulated by the cooperation of a sufficient number of employees, their employers, the respective industrial physicians and an unbiased competent group, commission or committee. Such a committee, group or commission should have a fair representation of obstetricians and gynecologists. The government or some private agency could make a valuable contribution through adequate support for a thorough study on causes of absenteeism of women employees. With several million women in industry an enormous number of days lost must be expected unless and until the causes can be reduced or eliminated. The number of women serving in the armed forces could be used for observations on problems of menstrual abnormalities, for these are normal healthy women. Any lesson learned even with this group could be applied to others. The first step is to get facts, for ideas are unreliable.

The placement of women in industry, the health maintenance program and working conditions for female employees have been elaborated on by others.

Since the employer must use to the best advantage all women employees, since replacements are not readily available, specific problems are truly important. It is common policy for most industries or industrial physicians to refer the employees to competent physicians for the personal problems of the employee. The industrial physician, directly or through councilors or matrons, may learn of employees who would benefit by consultation with the employee's own physician. Specific problems include menstrual disturbances (amenorrhea, menorrhagia, and metrorrhagia and dysmenorrhea), the menopause and pregnancy. Menstrual and menopausal disturbances are symptoms. First, it must be stated that present day information indicates that ordinarily menstrual and menopausal disturbances are not the result of employment. A prospective employee may fail to reveal her catamenial distresses or abnormalities, particularly if she suspects that such an admission would be unfavorable toward her employment.

MENSTRUAL DISTURBANCES

A. *Amenorrhea*.—If one excludes pregnancies and the menopause there are comparatively few instances of amenorrhea in the fully matured woman. Amenor-

rhea may occur in the teen age women, but it is usually not significant. Even so, Jameson⁴ and Hessektine and Spear⁵ recorded instances in which amenorrhea was the first or early symptom of pulmonary tuberculosis in women under 25 years of age.

It is general knowledge that tension, worry or undue excitement may be associated with either amenorrhea or a menorrhagia. Younger women in positions of responsibility may manifest such physiologic behavior. Anesthetists, instrument nurses and airline stewardesses have been typical examples. There is no reason why young women in other industries should not be potentially subject to the same reactions. A change of schedule or a transfer to another institution, although one may be doing the same work, may relieve the condition promptly. This correction can be expected only in the absence of organic states. Organic causes must be excluded. This is the function of the employee's personal physician.

B. *Metrorrhagia and Menorrhagia*.—Metrorrhagia and menorrhagia must be considered as a symptom of an existing pathologic condition within the individual. Menorrhagia and metrorrhagia should be considered symptoms of a serious existing condition such as cancer and other neoplasms, especially in the late childbearing years and at or after the menopause. There are no data to indicate that amenorrhea, menorrhagia or metrorrhagia results from employment or comes about because of injury or industrial accident. Each patient should be promptly referred to her physician or obstetrician and gynecologist for appropriate diagnosis and therapy.

C. *Dysmenorrhea*.—Dysmenorrhea is a problem in industry, for it causes a certain amount of absenteeism with some women. As a rule, each industrial organization has developed its own method of caring for women who develop symptoms while at work. Most plants are trying means to keep the employee on the job. The Committee on Health of Women in Industry² reported that:

Many women have little or no incapacitation during menstruation. Those with mild distress may be benefited by dietary improvement, by the avoidance of unnecessary physical and strenuous activities for a few days prior to the expected period or by the administration of mild sedatives and analgesics under the direction of the plant physician or the employee's personal physician.

Severe cases of dysmenorrhea may require the attention of the specialist. Dysmenorrhea is a symptom and results from many conditions such as pelvic inflammatory states, endometriosis, pelvic neoplasms, cervical stenosis, maladjustments, hormonal imbalance, migraine and allergic states. Adequate rest facilities at the plant are desirable, and a brief rest may cause only a slight interruption in the day's work rather than a loss of several hours. Hot applications to the lower abdomen or back may be helpful. Stimulants, as coffee, tea or other hot drinks, are sometimes beneficial.

Hundley, Krantz and Hibbitts⁶ claim that secondary dysmenorrhea offers little difficulty for it can be easily eradicated, but that primary dysmenorrhea presents many problems demanding thorough study before treatment is instituted. They continue with the thought that no panacea has yet been discovered. Browne⁷

suggests that 65 per cent of all women between puberty and the menopause suffer from some monthly discomfort. Such suffering might refer to coincidental headaches, mammary engorgement and tenderness, pain in the legs or distress in the lower abdomen or lower back. Those subject to "menstrual" headaches or severe lower abdomen distress will be the major contributors to absenteeism.

Most of the hormones have been used in the treatment of dysmenorrhea. The temporary value and limitations of this therapy have become evident. Balanced reports have come from the pens of Fluhman,⁸ Novak,⁹ Kurzrok and Birnberg,¹⁰ Sturgis and Meigs,¹¹ Salmon, Geist and Walter¹² and many others.

Cannon¹³ admits that psychologic factors may augment the intensity of dysmenorrhea pain. Meanwhile, Wittkower and Wilson¹⁴ found that as children the dysmenorrhea group showed psychologic maladjustment four times as often as the control group, and as adults the dysmenorrhea patients showed a high excess of two main personality groups. Additional support to the psychogenic factor comes from Boynton and Winther¹⁵ by their therapeutic controls, in which 8 per cent on placebos reported complete relief.

Miller¹⁶ stressed the importance of recognition of overlapping, of predisposing and of causative factors and the need for rational therapy based on a knowledge of fundamental causative factors.

Black,¹⁷ Colcock,¹⁸ Meigs¹⁹ and Marshall and Poppen²⁰ resorted to presacral neurectomy with good results, but each warns that the need is only for the severely affected but infrequent patients who do not respond to simpler and safer therapies.

It is common knowledge that with general physical and psychologic improvement a considerable percentage of women benefit or are relieved. Thyroid extract should be used only when the basal metabolic test may indicate a hypothyroidism. Thyroid extract may give remarkable improvement to teen age women who have a hypothyroidism. Others may by dietary balance and improvement gain as much relief. Still others may avoid incapacitation through the appropriate dosage of sedatives, as phenobarbital (0.0325 to 0.065 Gm.) once to twice daily, beginning a few days before the expected onset of the catamenia and continued through the period of expected distress. The elimination of undue physical activity with adequate sleep favors normalcy.

Analgesic drugs single or in combination may give some relief but unpredictably so. Antispasmodic (mydriatics included) may eliminate pain caused by spasm. The principle is to correct or alleviate the cause of the dysmenorrhea rather than to treat the symptoms.

The plant may have rest rooms where women who become ill may have a brief rest period. Often a short interval of rest will permit the employee to return to her routine work, thereby contributing to better production and saving the employee loss of pay. Obviously the plant physician may need to give first aid care for those who become ill while at work. Every one knows the importance of keeping people regularly at work as many days as possible.

The extreme shortage of labor has encouraged each industry to consider carefully the problem of dysmenorrhea in its employees. Tuttle²¹ has found it expedient to make a thorough pelvic examination and refer to gynecologists those who have repeated attacks of dysmenorrhea. He reduces the absenteeism from dysmenorrhea "largely by checking up on repeaters. . . ." The special attention which the medical department has given to the menstrual irregularities has benefited both the United Air Lines and the employees.

Absenteeism causes concern to the industrial physician because it requires medical attention periodically, to the employer because of interference with production and to the employee because of loss of pay through lost work. From the foregoing it is evident that dysmenorrhea is not an occupational disease and thus belongs to the private physician, either the employee's personal physician or an obstetrician and gynecologist.

Most women subject to menstrual pain can be benefited or relieved by adequate and appropriate therapy. The exact determination of the underlying cause of dysmenorrhea is the first step in the therapy.

MENOPAUSE

The menopause is the physiologic end of reproduction. The transition may be associated with symptoms of variable and even extreme degree. Many, if not most, women go through the menopause peacefully and without distress or annoyance. The latter group experiences little or no reaction in the routine of life. Unfortunately, some women at the climacteric suffer vasomotor and emotional instability. These reactions reveal themselves often under the stress of excitement and maladjustment. The excitement may occur in pastime or recreational activities as well as in necessary daily routines, such as shopping and home work. Many activities commonly indulged in by women may be disturbing at this period of life. Any distracting noises, conflicting personalities, maladjustment and like factors at the plant can activate or accentuate these menopausal symptoms but do not produce the primary condition. Thus, menopausal symptoms are essentially a personal condition and not an industrial malady.

It seems that proper placement is an important phase in keeping the women steadily employed. Reports come out that women in the menopause may and do work very well. Those who were previously employed continue in their regular work. Change or transfer to another type of work appears to be very seldom indicated but may be appropriate occasionally.

21. Tuttle, A. D.: Unpublished data.

The employee may because of her emotional instability become irritable and thus lessen production. These same women may become provoked, angered or excited more readily than before the onset of the climacteric. Unfortunately, not all women are aware of their unsettled emotional state. Unfortunate also are those who are aware of it but have no control of the situation. These women may be completely relieved by estrogenic replacement. Diethylstilbestrol by mouth is quite efficient, easily taken and economical for the employee. The dosage may vary from 0.5 to 1 mg. daily for several weeks (eight to sixteen) followed by a progressive and graduated reduction but under the direction of the employee's personal physician. Occasionally there may be some vaginal bleeding caused by the withdrawal of the drug. A recurrence of this bleeding should be looked on as a serious symptom, possibly uterine or cervical cancer, until by curettement and biopsy it is excluded. The administration of estrogens before cessation of menstruation may be followed by greatly altered menstrual periods and cycles, and thus estrogens should be withheld until the menstrual periods have vanished. Sedatives, as phenobarbital, may serve better while menstrual periods occur and may be an adjunct to estrogenic replacement subsequently.

Women of the menopausal age may have vaginal wall relaxations and beginning prolapse, and thus their proper placement is particularly desirable. Pelvic examination of those approaching or through the menopause could elicit early vaginal wall relaxation, beginning prolapse and other gynecologic conditions which may become progressively worse.

PREGNANCY

Pregnancy is a biologic and physiologic function of mature women. This function may interfere with normal activity and employment. Many pregnant women work about their homes and in their gardens, but full shift of work at the plant and also as many hours at home work is undesirable and should be avoided. The type of work should be individually considered for each gravid employee. Individualization is often disturbing and confusing in a large industry, but with the cooperation of the employee's physician there should not be great difficulty. The evaluation of type of work must be based on the employee's ability to perform the work with reasonable safety to herself and to the pregnancy. As the pregnancy advances the woman becomes more awkward and hence must be protected more carefully from falls. She should not climb or walk where delicate balance is involved or particular hazards exist. Regular shifts will be conducive to regular rest. Every pregnant employee must be protected particularly from toxic substances.

The employee should consult her own physician or obstetrician early in the pregnancy (within eight to ten weeks from the last menstrual period). The physician should take a complete antepartum history, do a complete physical and pelvic examination and determine the pelvic measurements. A routine urinalysis, a hemoglobin or cell volume determination and a white blood cell count should be completed at the first visit and a serologic test made for syphilis. Other tests should be made when indicated.

The Committee on the Health of Women in Industry²² urged that "each employee inform the proper authority in the industry about her pregnant state within the first trimester (three months), that she obtain a statement from her physician to the effect (1) that her work is not contraindicated and (2) that she

may work not longer than a given period of pregnancy. If contraindications to work arise, the employee's physician should notify the employer.

"The patient should not return to work until six weeks after delivery and then only when her physician notifies the employer that she may return. If her return to work at six weeks is inadvisable because of her own condition or because her baby actually needs her at home, she should request further extension of time."

The committee² felt that discontinuance of work in the last trimester or earlier would be desirable but by all means by the thirty-second week of pregnancy.

The antepartum care should be carried out by the employee's own obstetrician, for he is prepared to give antepartum care and he has the responsibility of the parturition. In early and mid pregnancy visits to the obstetrician at three week intervals may be sufficient for normal women. The program will vary with conditions or complications. Any emergency at the plant can and is treated by the plant physician until the private physician can take over.

The American committee approved the plan drafted by Danforth, Kosmak De Normandie and Adair²² for maternal care. Care of complications must receive special consideration. The management of obstetric hemorrhages, toxemias of pregnancy and puerperal infection has been outlined by Williams, Mussey and Falls respectively.²³

The Committee on the Health of Women in Industry² made special comment, as:

Unintentional abortion is the most likely obstetric complication in the first trimester of pregnancy and it may have no relationship to the employment. These accidental abortions result perhaps more often from abnormal or diseased ova and not because of work or activity. Excessive vomiting is the second most likely problem in the first trimester.

The last trimester is complicated most often by toxemia of pregnancy, placenta previa or abruptio placentae. All of these obstetric emergencies are incompatible with employment of any kind and need immediate treatment.

The midtrimester is a comparatively safe period, but any complication may arise at this time, as well as any other, such as anemia, hypertension and nephritis, pyelitis, neoplasm (both benign and malignant) and many other conditions.

Other complications will also alter the program. Genital tract infections may require treatment from every two to seven days. Antisyphilitic treatment should be weekly. The management of medical complications will necessitate a specially devised program. In the event of excessive weight gain or evidence of toxemia, special instructions must be given. These are only some of the conditions that the obstetrician may encounter in the care of his patients.

SUMMARY

Women can work efficiently in many industries but, because of physiologic behavior peculiar to them, attention to their peculiarities should reduce the amount of absenteeism and also protect the obstetric and gynecologic health of the individual.

The cause of amenorrhea (gravid and menopausal causes excluded) should be adequately investigated.

Menorrhagia and metrorrhagia should be looked on as a serious sign until such condition as cancer, other neoplasms and other conditions have been eliminated.

Primary dysmenorrhea may require special study. Secondary dysmenorrhea is associated with many conditions and thus its successful therapy will depend on correction of the underlying factors.

22. Adair, F. L.: *Maternal Care*, Chicago, University of Chicago Press, 1937.

23. Adair, F. L.: *Maternal Care Complications*, Chicago, University of Chicago Press, Chicago, 1938.

The menopause may be associated with emotional instability.

Pregnancy will require special consideration.

Menstrual abnormalities, the menopause and pregnancy are nonindustrial conditions. These conditions are classified as personal conditions, and thus obstetric and gynecologic care should be administered by the employee's personal physician.

Private physicians should acquaint themselves about industrial problems in relation to obstetric and gynecologic conditions in order that they may collaborate with industrial physicians in common problems.

Until factual and sufficient data can be procured and published on pregnant states, menopausal symptoms and menstrual abnormalities in relation to employment, directions and recommendations on employment, placement, safeguards, reduction of absenteeism and introduction of health measures will be guided by ideas and opinions.

Some agency, private or governmental, should support studies to supply this badly and urgently needed information. Fair and unbiased observers, committee or commission, could compile and analyze the data. From such a basis the employees would benefit by the gains for their welfare, and the employer should benefit by a reduction of absenteeism. The industrial physician would be aided by specific findings, and the private physician could prescribe more reliably for his employed patients.

APPENDIX

From the Monthly Report on the Labor Force, Department of Commerce, Bureau of Census, Washington, D. C., Dec. 10, 1943, special surveys MRLF, No. 18, the following estimates of female employees are listed:

July 1943, 17,100,000 employed, 600,000 unemployed.
November 1943, 16,000,000 employed, 300,000 unemployed.
December 1943, not yet available.

The difference for the greater number for the summer employment was explained on the basis of the use of the 14 to 19 year olds. Unless an unexpected and sudden rise occurs, the predictions for December 1943 cannot be fulfilled.

5848 Drexel Avenue.

ABSTRACT OF DISCUSSION

DR. GOODRICH C. SCHAUFFLER, Portland, Ore.: Dr. Hessel-tine merely mentions the matter of preemployment physical examination and health follow-up and leaves us with the inference that it is the more or less universal practice. This is not the case, particularly in so-called mushroom war industries in the Western area. Pressure could be put on laggard industries to install such systems. Well integrated programs in operation have proved their value. Basic thinking in the matter involves, first, the creation of a central committee endowed by funds from all contingent organizations and vested with authority to act.

DR. GEORGE W. KOSMAK, New York: It is evident that the physiologic status of women must be given definite thought and consideration when compared with that of men, and social responsibilities likewise cannot be neglected. This phase has not been accorded sufficient importance in the general desire for developing more manual power in the nation and in the opportunities opened up for more gainful employment. No matter how great the endeavor may be to place men and women on the same plane, politically and economically, there still remain those anatomic and physiologic differences in the sexes which cannot be eliminated entirely. This is evident from the proposals suggested in Dr. Hessel-tine's paper for the special

handling of the medical problems arising from the wider employment of women in various, particularly wartime, industries. Such admissions show the need of a changed approach to a subject which in the course of time may bring about conditions that do not compensate for immediate economic advantages which may have resulted. Hitherto women in industrial occupations have not been subjected to the same stresses and strain, and their labor has been adjusted to what it was believed they could do within their physical limitation. Now they are being required to do heavy and more hazardous work as generally understood and on a plane with men, and with equal pay. For the mutual protection of industry and the women to be employed, and should this necessity for women's work continue, will it not become necessary before employment to devise methods of physical examination to avoid breakdowns? For while immediate demands for her labor may appear primary, the fact cannot be set aside that woman has certain functions which are paramount and which in their widest sense must not be subordinated. If conditions peculiar to the sex are to be determining factors in assuring successful and continuous employment, with lessened absenteeism due to these, may it not be wise to develop standards to provide the means for more extended preliminary physical examinations? Such standards have been worked out by a committee from the New York Academy of Medicine and include a careful history as well as a physical examination of all candidates for employment, particularly in the hazardous occupations. Whether industry as a whole will undertake this precautionary measure to avoid accidents, breakdown or absenteeism remains to be seen. However, as I have also noted, the more extended employment of women has taken from them social responsibilities which it is to be hoped may be restored when demand on their contribution to the war effort has become eliminated with the advent of peace.

DR. J. C. LITZENBERG, Minneapolis: Employment of women in industry presents somewhat different problems from employment of the same women not so employed. This is not only because they belong to the so-called weaker sex and are less robust than men but because they are generally less efficient and employable than men in the heavier industries. Employed women offer other problems because they are potentially child-bearing persons subject to gynecologic, menstrual and menopausal disturbances, or they may become pregnant, any of which facts may reduce their efficiency or cause absenteeism or totally incapacitate them. Nevertheless women must be employed in industry to alleviate the manpower deficiency. But it is not as simple as that, for, "man for man," the woman cannot equal her stronger brother except in the not-too-heavy industries. In spite of physical limitations, she has proved surprisingly efficient and valuable in keeping up production, quite as efficient in many types of work as a man. Inevitably, however, these specific problems of women in industry do interfere with production. All out war production is quite as important as all out frontline effort. The latter is impossible without the former. It seems impossible to approach the needed production without the employment of even more women. At the beginning of 1944 it is estimated that 18 million will be employed, of which number 3 million will be in exclusive war industries. Dr. Hessel-tine quotes Browne as saying that 65 per cent of women suffer from menstrual discomfort, which may reduce efficiency and be a fruitful source of absenteeism or even incapacitation. One can easily imagine that among so many women much absenteeism will be the result to say nothing of other gynecologic disturbances. Dr. Hessel-tine's most constructive suggestion concerns the lack, at present, of exact information about the influence of these specific conditions on women in industry. Much medical information is available about these conditions on women in general, but no adequate data of their influence on industry itself are at hand, such as the amount of absenteeism caused by menstrual irregularities and distress, the menopausal syndrome or pregnancy. Until factual and sufficient data can be procured on the effects of pregnancy, menstrual abnormalities and menopausal symptoms in relation to employment, safeguards and reduction of absenteeism, the introduction of health measures will still be guided by ideas and opinions rather than by data supported by scientific conclusions.

THE USE OF BASAL TEMPERATURE GRAPHS IN DETERMINING THE DATE OF OVULATION

PENDLETON TOMPKINS, M.D.
PHILADELPHIA

A simple method for determining the time of ovulation has been discovered but unfortunately has not been brought to the attention of clinicians at large. It is based on variations in body temperature during phases of the menstrual cycle. My purpose in this presentation is to describe the technic of securing graphic records of daily basal temperatures, to discuss the interpretation of these records and to demonstrate their usefulness in indicating the date of ovulation by showing graphs submitted by patients under treatment at the present time.

In 1904 van de Velde¹ discussed the variations in body temperature during phases of the menstrual cycle. Since that time at least a score of excellent papers have dealt with the subject, particular emphasis being placed on the correlation of temperature changes and ovulation. Barton² gave a historical review and correlated temperature and electrical potential variations due to ovulation. D'Amour³ compared temperature records with other methods of determining ovulation time. Martin⁴ has shown an accurate correlation between phases of the endometrium and the temperature curve. Greulich and Morris⁵ made a convincing clinical test of the accuracy of temperature records as an indication of ovulation. Laparotomies were performed on 14 patients whose temperature records were available. In 8 cases ovulation was expected, in 6 it was not. Inspection of the ovaries at laparotomy confirmed the prediction in every case. Harvey and Crockett⁶ presented temperature records of 1 patient over a thirteen month period and gave an involved mathematical analysis of the variations observed. Lyon⁷ discussed the evaluation of dysmenorrhea by temperature records. Mocquot and Palmer⁸ reported the effect of endocrine therapy on basal temperature. Palmer and Devillers,⁹ Williams¹⁰ and Allan Palmer¹¹ illustrated their reports with graphs similar to those presented here. Rubenstein¹² is the most

enthusiastic American investigator. Zuck¹³ and Williams and Simmons,¹⁴ among others, have made clinical use of the method. Barton² and Vollmann¹⁵ furnish extensive bibliographies.

All this literature may be summed up thus: A record of body temperatures taken daily under standard conditions shows a typical curve during the menstrual cycle. The temperature is relatively low during the first part of the month, drops to a minimum about the time that ovulation occurs and rises definitely thereafter to a relatively high level, which is maintained until the next menses, when the temperature drops abruptly. Before the menarche, after the menopause, and in men, similar temperature fluctuations are not found. If conception occurs, the temperature will remain at the high postovulation level. The important feature is the rapid rise in temperature at ovulation. Many clinicians

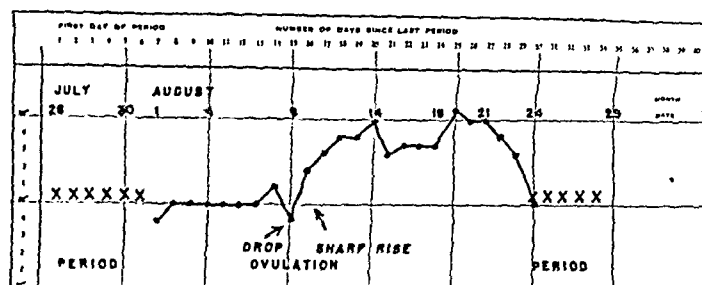

Chart 1.—An ideal temperature graph submitted by a patient. The cycle was 30/5-6. Note (1) the relatively low temperature prior to ovulation, (2) the slight drop on August 9, which occurs at ovulation, (3) the sharp rise following ovulation, (4) the relatively high level after ovulation and (5) the sharp drop when menstruation begins. The temperatures shown are exactly those submitted by the patient but have been regraphed and annotated for publication.

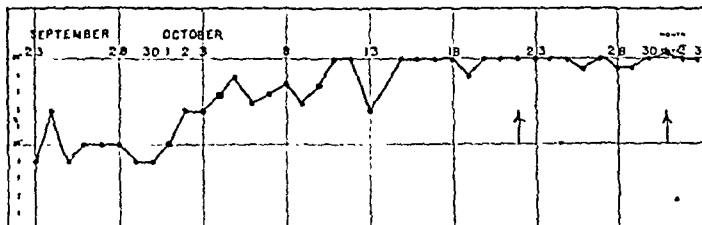

Chart 2.—Use of the temperature graph in sterility studies on a patient with very irregular menses. The patient, aged 22, was married in 1940 and had not conceived probably because her husband was at sea much of the time. Menstruation had occurred on May 11, 1943, June 21, July 16, August 15 and September 7. She first consulted me on September 20. It appeared that the chief problem was to select the fertile period, a problem which could not be solved simply by using the calendar because the intermenstrual interval varied from three to six weeks. Accordingly a temperature graph was started. As shown, the rising temperature on October 2 suggested ovulation, and coitus was advised. On October 22 the patient reported by telephone that the graph showed a sustained high temperature. A tentative diagnosis of pregnancy was made (first arrow). Pelvic examination on October 25 was indeterminate. On November 1 the Friedman test was reported positive (second arrow), and pregnancy has since proceeded uneventfully.

attest the practical accuracy of this fact; several laboratory minded writers question it. The remarkable observation is not that temperature records sometimes fail to indicate ovulation but that they ever indicate it. The method is so simple, so inexpensive and so helpful that the utmost use should be made of it. When temperature graphs are used in the study of sterility it is taken for granted that all other well known investigations, such as sperm counts, tubal insufflation and basal metabolism tests, are carried on as usual. The basal

temperature record is not a substitute for any other commonly performed study: it is an adjunct.

In order to secure good records I have found it most helpful to have 8½ by 11 inch forms printed on grid paper. Two sheets are furnished each patient. One blank form is for the patient's use in drawing a graph;

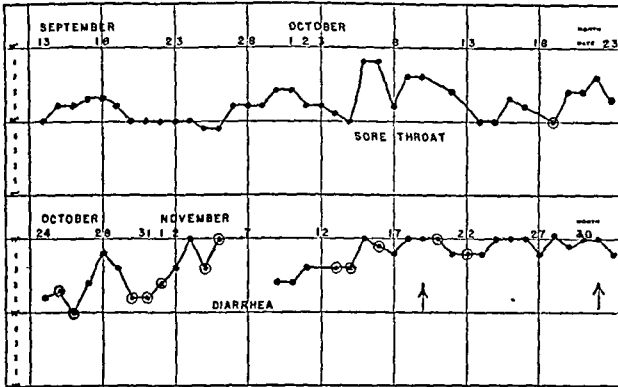

Chart 3.—Use of temperature graphs in sterility study of a patient with amenorrhea attributed to premenopausal changes. The patient was a nulligravida aged 42, married in March 1943. Menstruation had occurred "regularly every month" previous to 1943. The last periods were dated December 1942, March 9, 1943, May 25 and July 15. At the first consultation on Sept. 9, 1943 it appeared that the problem was to detect and take advantage of any subsequent ovulation which might occur. Both the patient and I felt that the menopause was beginning. The temperature graph shown here was commenced on September 13. No variations in temperature which suggested ovulation occurred until late October, nor did menstruation develop. On September 15 and again on October 15 a thin stain appeared, but this seemed at the time to be due to coital trauma rather than to menstruation. I believe the question cannot be answered with certainty. Since the graph for the first thirty five days showed no temperature rise which could be construed as indicating ovulation, the patient was instructed to have intercourse when the temperature reached its lowest point and to record the fact by encircling the temperature notation. This she did, beginning October 19. Study of the graph reveals an interest in recreation as well as in procreation. However that may be, the sustained high temperature on November 19 (first arrow) suggested that conception had occurred. Pelvic examination on November 23 was indeterminate, but the Friedman test was positive on December 1 (second arrow). Pregnancy is proceeding normally.

the other sheet contains instructions and, on the reverse, an example of a properly drawn graph. These forms have provided excellent records which are easily read both by the physician and by the patient. Moreover, they have increased the patient's understanding of the problem and aroused her interest in it. I strongly recommend the use of forms.¹⁶ In this work it is essential to secure good graphs, and these are not forthcoming until the patient has a clear idea of what is wanted, and why. It will not suffice for the physician

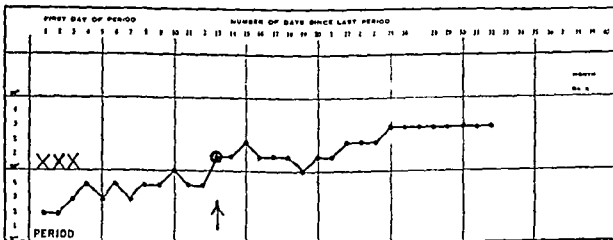

Chart 4.—Successful artificial insemination timed by the graphic method. Periods very regular, twenty eight to thirty days. Artificial insemination had been unsuccessfully attempted on two previous occasions on the 14th day before the expected period. As the graph shows, fruitful insemination (arrow) occurred fifteen to seventeen days before the period was due. Note the sustained elevation of temperature, which is typical of early pregnancy. Pregnancy has progressed to the fifth month uneventfully.

to instruct the patient orally or to tell her to "write down the temperature every day" or to "draw a graph." A list of figures is not sufficiently meaningful to patient

or doctor; from the practical standpoint it is essential to plot the data as a graph. Further, the graph must be planned so that the temperature variations are readily apparent. Before proper forms were printed, patients would present neat graphs plotted precisely but showing the temperature curve as an almost straight line or sometimes as an apparently hectic fever. Not until I had laboriously rescaled and replotted such a graph could it be read. The whole purpose of this report is to show how simple it is to secure and read temperature graphs, and the secret of the method (which is no secret) is to give the patient proper graph paper forms and complete written instructions. The instructions to the patient follow; remarks contained in the brackets do not appear on the sheet which the patient receives:

Conception is most likely to occur if intercourse takes place at approximately the time when the ovum is released from the ovary (ovulation). In most women ovulation occurs about fourteen days before menstruation, but this may not always be the case. It is particularly difficult for patients whose menstrual interval varies considerably from month to month to calculate the date of ovulation. Fortunately it is often possible to determine the probable time of ovulation (and hence the time when intercourse is most likely to result in conception) by a simple method.

Theoretically the normal temperature of a healthy person is 98.6 F. Actually there are continual slight variations from this figure. It has been found that woman's temperature is

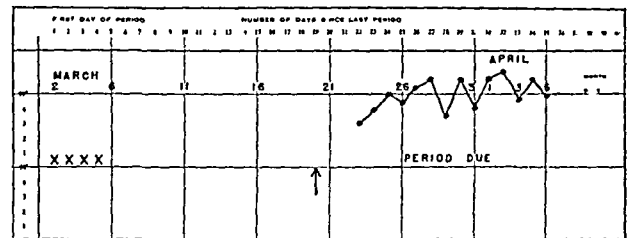

Chart 5.—Use of temperature records as an aid in the early diagnosis of pregnancy. The patient, a nulligravida aged 24, had been studied and treated by Dr. Douglas Krumbhaar of Boston because of sterility. When she moved to Philadelphia in March 1943 Dr. Krumbhaar requested that an endometrial biopsy be taken in the last week of the menstrual month. The cycle was 24/5. Since the previous periods occurred on February 4 and March 2, and the next period was expected March 26, the patient reported for biopsy on March 20 (arrow). I thought she might already be pregnant and by telephone obtained Dr. Krumbhaar's consent to deferment of the biopsy. The patient began a graph, which promptly revealed the high temperature level typical of pregnancy. The tentative diagnosis of pregnancy was confirmed when the period was missed. Allowing for the twenty-four day cycle, term was calculated as December 5. The patient was delivered uneventfully by Dr. Krumbhaar on Nov. 28, 1943.

lower during the first part of the menstrual month than it is during the last weeks of the month, and further, that the transition from a low level to a higher level occurs about the time of ovulation. It is therefore possible by keeping a graphic record of the body temperature to identify, in many cases, the date of ovulation. The variation in temperature is slight, only a few fifths of a degree, so it is essential that the temperature be taken with the utmost practical accuracy. In utilizing the temperature method for determining the date of ovulation the following rules are to be observed:

1. Take the temperature rectally with a blunt tip rectal thermometer for five minutes by the clock immediately after waking in the morning and before arising, eating, drinking or smoking (!). [Some investigators advise that the temperature be taken at the same hour each morning. I myself would prefer to have the temperature recorded when the patient wakes up in the belief that a more significant figure is recorded at 10 a. m. on a Sunday morning after a gay evening than at 7 a. m. when the patient has only had three or four hours' sleep.]

2. Note the temperature immediately by a dot on the graph. If the temperature so recorded differs much from previous readings, and particularly if it is lower than previous readings, the thermometer should be shaken down and reinserted for an additional five minutes by the clock and the reading checked before it is recorded permanently.

3. Any recognized cause for temperature variation should be noted on the chart, for example, a cold, grip, indigestion or even a hangover.

4. Some women can detect ovulation by noting a twinge of pain low on one side of the abdomen. Others have a drop or two of vaginal bleeding at the time of ovulation. If either of these manifestations is present, note it on the chart on the day of occurrence.

5. Chart the temperature by means of a small dot. If intercourse has taken place in the previous twenty-four hours, encircle the dot.

6. It is not essential to take the temperature during menstruation. Mark the first day of menstruation at the extreme left of the chart and commence a new graph when the flow has diminished. [In general I have not found it necessary to secure the temperature during menstruation, although potentiometer studies are reported to have shown that ovulation may occur during menstruation. If the graph gives no indication of ovulation between periods, then of course it would be wise to secure the temperature during every day of the month.]

7. It is necessary to continue the graph for at least two menstrual months before it is of much value. After this time it is usually possible to predict when the temperature will rise (ovulation). Sexual abstinence for several days before ovulation allows time for the male to store up sperm and probably increases the chance of fertilization.

8. If the temperature shows a rise of 2 or 3 fifths of a degree, and if this rise corresponds with a similar rise in the previous menstrual month and is not due to illness, then it can be assumed that ovulation is occurring and that intercourse is most likely to be fruitful. Intercourse oftener than once in twenty-four hours is probably unnecessary. [It is supposedly true that ovulation is indicated by the lowest temperature recorded. However, it is impossible to advise patients to have intercourse when the temperature is lowest, since it is impossible to determine in advance when the lowest point is reached. For this reason I have advised intercourse when the temperature shows a rapid rise.]

The accompanying charts show the sort of graphs drawn by patients, and the value of the graph is explained in each instance.

I believe that basal body temperature graphs very often indicate the date of ovulation. These graphs have been useful to me in suggesting to childless couples the time of maximum fertility, in determining the date for endometrial biopsies and in setting the date for artificial insemination in 2 cases, both of which were successful after previous failures. The graphs may also be used to detect the "unsafe period" for those who do not use contraceptive measures. In several cases an early correct "diagnosis" of pregnancy has been made before the pelvic findings or the Friedman test was positive. The method may be put to many other uses; for example, it should be helpful to investigators searching for very early ova.

In reviewing the literature I was struck by the fact that no one denies the usefulness of graphic temperature records. The method is doubted, but apparently without a fair trial. There is criticism on the grounds that the record of temperatures will not be accurate (but it is accurate enough to be useful) or that it is troublesome to secure (but nothing is too much trouble for the woman who wants a child) or that it is not as precise as hormone assays (but how much less expensive) or that electrical methods are more scientific (how many clinicians own potentiometers? ¹⁷ All of us have thermometers). In short, the method deserves more general use.

THE DIURETIC EFFECT OF ASCORBIC ACID

PRELIMINARY REPORT ON ITS USE IN CARDIAC DECOMPENSATION

CARL F. SHAFFER, M.D.

OMAHA

The first reference in the English literature to the diuretic action of ascorbic acid was made in a study of normal persons without edema.¹ This had previously been described by German authors in the experimental animal and explained as a "polyphasic effect of ascorbic acid on the colloid osmotic pressure of the blood."² These observations have been applied to persons with edema from various causes; the present report concerns patients in cardiac decompensation.

The nutritional status of a person in respect to vitamin C can be estimated by his response to a test dose of ascorbic acid. The size of the dose varies with the route of administration, and the response, or amount of renal excretion, varies with the tissue vitamin content. If this substance is given by mouth there is almost complete absorption and the maximum rate of excretion normally occurs in three to six hours; if given by vein the maximum excretion is in one to two hours.³ Using either method, the rate varies inversely with the extent of tissue concentration.

It has been demonstrated that, regardless of the state of vitamin C reserve, a person can be saturated by a peroral dose of 3 Gm. of ascorbic acid in six days.⁴ The diuretic action corresponds to the period of saturation. This is usually on the third or fourth day if there is a normal reserve.⁵ If given parenterally, depending on the size of the intravenous dose, a person can be saturated in shorter time. But in this instance there is no appreciable diuretic effect, possibly because of too rapid excretion of ascorbic acid.⁶

CLINICAL STUDY

A series of 10 patients with peripheral edema were given a daily supplemental dose of 500 mg. of ascorbic acid by mouth in divided quantity.⁷ There were 5 men and 5 women, with an age distribution of 20 to 60 years, representing the common etiologic types of cardiac decompensation. Each patient remained in bed, received a standard hospital diet with a measured vitamin C content (50 mg. a day) and had a relatively stable fluid balance for three days prior to giving ascorbic acid. All were receiving a maintenance dose of digitalis, and no other diuretic was used during the six day period of study. The fluid intake was regulated at 1,500 cc. in twenty-four hours, and the urine output was recorded.

All patients had a small diuresis as determined by comparing the three day average output at the height of response (usually the third, fourth and fifth days) to the same period average before giving ascorbic acid. The actual increase was from 250 cc. to 1,000 cc. in seventy-two hours, not as great as expected, based on observations of normal subjects. The results corre-

sponded in general to those reported by Evans⁸ in a similar series of patients. He concluded that ascorbic acid was a more effective diuretic than digitalis but less effective than the adjuvant diuretics commonly used.

Another 10 patients with edema were given a daily supplement of 500 mg. up to 3 Gm. by vein, using the same control procedure, without appreciable diuresis.

The remaining alternative was to give a combination of diuretics. Since, as a whole, the mercurials are most effective for the release of edema of cardiac origin, ascorbic acid was added to mercupurin (500 mg. to 2 cc.). Each of this series of 20 patients had received at least one injection of mercupurin before being given the combination.

Three fourths, or 15 patients, had a relatively large diuresis of from one-half to two and one-half times greater than when mercupurin was used alone, as determined by comparing the first day output in each instance. The actual increase was from 500 cc. to 2,000 cc. in twenty-four hours. A smaller output was noted in 5 patients. In 2 of these mercupurin by itself had caused no significant diuresis, and 2 others had previously received supplemental vitamin C by mouth. It was noted that in patients wherein edema reaccumulated there was a progressively smaller response to injection of the combination at regular three day intervals. This was due in major part to a decreasing amount of fluid available for release and probably in part to increasing tissue saturation with vitamin C.

COMMENT

In animal experiments the blood colloid osmotic pressure determined by Govaerts' method subsequent to injection of ascorbic acid was usually increased but occasionally decreased or unaltered. Repeated daily injection caused a total increase but no cumulative effect. From these results it was concluded that this substance influenced osmotic pressure by a polyphasic mechanism.²

In additional experiments the blood plasma carbon dioxide combining power subsequent to injection was uniformly increased.⁹ This observation, also made in both of my series of patients experiencing a diuresis, is in direct contradistinction to an effect that acid-producing salts have in potentiating the mercurial diuretics.

SUMMARY

Ascorbic acid given by mouth resulted in a small diuresis in 10 patients with cardiac decompensation. When given by vein there was no appreciable similar effect. In combination with mercupurin there was a relatively large diuresis of from one-half to two and one-half times greater than with mercupurin alone.

The diuresis caused by ascorbic acid, based on studies in the experimental animal, is believed due to altered colloid osmotic pressure. It is not due to production of acidosis.

HEALTH HAZARDS ENCOUNTERED IN THE MANUFACTURE OF SYNTHETIC RUBBER

CAPTAIN REX H. WILSON

Assistant to Surgeon

* MEDICAL CORPS, ARMY OF THE UNITED STATES

The manufacture of synthetic rubber involves several chemical compounds which are toxic to man. A summary of the health hazards involved in the manufacturing process is warranted, as great quantities of synthetic material are being made.

This paper deals with experiences encountered in the manufacture of certain types of synthetic rubber. Sufficient time has not elapsed to enable these observations to be supported by comprehensive figures.

The principal chemicals used in the manufacture of synthetic rubber are (1) butadiene, which is also known as methyl allene and has a chemical formula of $\text{CH}_2:\text{CHCH}:\text{CH}_2$, (2) styrene, also known as vinyl

benzene, having the chemical formula  $\text{CH}:\text{CH}_2$, and (3) acrylonitrile, or acrylonitril-vinyl cyanide, which has a chemical formula of $\text{CH}_2:\text{CH-CN}$. In addition to these chemicals, polymerization catalysts such as hydrogen peroxide, sodium perborate, ammonium persulfate or organic peroxides or peracids and modifying agents—such as carbon tetrachloride, hexachloroethane, organic halogen compounds, trichloropropionitrile, sodium cyanide, mercaptans, xanthogen disulfides, thiuram disulfides and sulfinic acid are used. The chemistry of these groups of compounds has been fairly well described by various authors and will not be discussed here, since we are primarily interested in the hazards encountered in handling them.

I observed that workmen exposed to butadiene vapors complained of irritation of the eyes, nasal passages, throat and lungs. In some instances coughing was produced. A sense of fatigue and drowsiness developed in some. In all cases these symptoms disappeared on removal from the fumes. Subsequent exposures caused the same symptoms, but these did not appear to be exaggerated, indicating no cumulative action. All workmen who complained of symptoms were immediately examined. Physical examinations, including chest x-ray examinations, blood examinations and urinalyses, were all negative. Follow-up examinations were also negative. No skin effects were noted. No workmen were exposed to heavy concentrations of the fumes.

Styrene, because its chemical structure is similar to toluene, was primarily considered to be as toxic as toluene. This did not prove to be the case.

No workmen in my experience were exposed to concentrations of styrene over 500 parts per million. The presenting symptoms were irritation of the nose, throat and lungs. Coughing occurred in some cases. A mild conjunctivitis occurred in some cases. A feeling of lassitude and fatigue occurred in all cases. In several cases in which the skin came into contact with styrene, the skin was rough, dry and cracked. This was probably due to the styrene dissolving the natural oils of the skin.

Whenever workmen were exposed to styrene fumes and complained of toxic effects they were sent to the hospital for examination. In addition to a complete physical examination they also received a complete blood count, urinalysis and a chest x-ray examination.

At no time was any pathologic condition noted. Some of these workmen were observed for over a period of at least one year, and no chronic or cumulative effects were noted.

Liver or kidney damage might be expected to occur following exposure to high concentrations of styrene vapors. No pathologic change of this type was seen.

Acronitrile, because it contains vinyl cyanide and liberates hydrogen cyanide, is definitely a source of danger. It presents definite hazards of vapor toxicity and of toxic absorption. Every care was taken to prevent human exposure. In spite of all precautions, some workmen were exposed to mild concentrations. These workmen presented symptoms of nausea, vomiting and weakness. Headache, fatigue and diarrhea also occurred in some. All complained of nasal irritation and an "oppressive feeling" in the upper respiratory passages.

In several cases a mild jaundice appeared which lasted for several days. In 1 case severe jaundice appeared which did not disappear until four weeks had elapsed. The jaundice was accompanied by varying degrees of headache, prostration, nausea, vomiting, diarrhea and tenderness in the abdomen. In the mild cases without jaundice no physical signs were noted except occasional liver tenderness. All types of laboratory examinations were negative. In the more severe cases, that is, those in which jaundice was present, the blood icterus index varied with the degree of jaundice. Usually a low grade anemia appeared with the hemoglobin averaging 13 Gm. per hundred cubic centimeters of blood, the red blood cell count averaging 4,000,000 per cubic millimeter and the white blood cell count being slightly elevated, averaging 12,000 per cubic millimeter. The differential count was usually normal.

Analysis was usually normal except for an increased bile content. Stools were light in color. With treatment all cases returned to normal with the exception of the case of severe jaundice. In this case, after one year's time, lassitude and fatigue were still complained of, although no pathologic physical signs remained.

Fortunately no fatal cases occurred. This was probably due to the extreme care used in the handling of the chemical, thus avoiding lethal concentrations of the compound. As already stated, there is no question that sufficient exposure either to the vapor or through skin absorption would cause death.

The toxicity of the other chemicals used in the compounding of synthetic rubber is sufficiently known not to warrant their discussion here. Suffice it to say that they do possess toxic qualities sufficient to be a health hazard in themselves.

Several workmen permitted several types of synthetic elastic to be placed on their skin for a period of seven days. No reactions occurred.

TREATMENT

Exposure to any one of the aforementioned compounds is a serious thing. During the process of combination they still retain and perhaps enhance their toxic properties. As a matter of fact, most of the patients could easily have had exposure to several of the compounds simultaneously. Therefore all workmen were given a complete physical examination whenever one presented himself to the hospital. It was made a standard rule for all supervisors to send all exposed workmen to the hospital immediately. A complete laboratory examination was made, including a complete blood count, a blood icterus index and a urinalysis.

Chest x-ray examinations were also made routinely. If any pathologic change was noted the employee was immediately hospitalized. In any event he was sent home and not permitted to return to work until several days had elapsed, during which time he was kept under observation with repeated physical and laboratory examinations. Treatment was entirely symptomatic. Lacrimal irrigations, liquid petrolatum instillations in the nasal passages and small doses of acetylsalicylic acid for discomfort were given. Rest and fresh air were prescribed to all. A light diet was recommended. All of the jaundiced employees were hospitalized, and they were given intravenously 1,000 cc. of 5 per cent dextrose solution daily. Liquids were forced. Liver and iron was given, 12 capsules daily. A multiple vitamin capsule was given three times daily. The liver and iron and vitamin capsules were continued for several months after the patient became ambulatory. Length of bed rest varied from three to ten days. All patients were kept in bed until the jaundice and abdominal tenderness disappeared.

PRECAUTIONS

In my opinion the following general precautions should be observed in all plants manufacturing synthetic rubber:

1. A complete preemployment physical examination for all workmen including a complete blood count, urinalysis, blood icterus index, blood Kahn or Wassermann test and a chest x-ray examination. Evidence of chest, liver or kidney disease, syphilis or pregnancy should preclude employment.

2. All operating personnel should be examined every three months, this examination to include a complete blood count, urinalysis, blood icterus index and a chest x-ray examination. Evidence of organic pathologic change should be reason for immediate removal from the job.

3. All operating personnel should be impressed with the toxic hazards of the various compounds and taught to handle them properly.

4. A closed type of operation should be made mandatory. Continuous inspection of all equipment for possible leaks should be enforced.

5. A set of safety rules regarding the use of protective equipment (gloves, goggles, masks) should be posted at the danger spots.

6. Both personal and group safety equipment should be supplied as needed.

7. Adequate ventilation, both local and general, should be maintained at all times.

SUMMARY

1. Butadiene is a light narcotic poison with no apparent danger to light exposures.

2. Styrene is to be considered as a toxic compound. Mild exposures do not produce any pathologic effects. Heavy exposures may cause permanent damage, but so far this has not occurred.

3. Acrylonitrile is extremely toxic both from vapor toxicity and from toxic absorption. Even mild exposures are dangerous.

4. Other compounds used in the manufacture of synthetic rubber are to be considered to be toxic and precautions taken in their handling.

5. Treatment of exposed cases is chiefly symptomatic.

6. All operating personnel should receive thorough preemployment examination and a complete periodic check-up every three months.

7. Adequate ventilation is to be supplied at all times.

8. Constant inspection of all equipment should be maintained.

9. Personal and group safety equipment should be supplied and their use enforced.

Clinical Notes, Suggestions and New Instruments

MENINGOCOCCIC CONJUNCTIVITIS

MAJOR ROGER D. REID, SANITARY CORPS, OFFICERS' RESERVE
CORPS, AND CAPTAIN LEWIS H. BRONSTEIN, MEDICAL
CORPS, ARMY OF THE UNITED STATES

When gram negative intracellular and extracellular diplococci are demonstrated in a smear from the conjunctiva showing purulent conjunctivitis, the presumptive diagnosis of gonorrheal ophthalmia is almost universally made. Except in rare cases it has not been considered necessary to make detailed bacteriologic or serologic studies of the organisms found. This attitude may have been due in the past to difficulties in culturing the neisserian organisms and in their serologic identification. This is no longer a legitimate excuse, since in recent years cultural and serologic identification of these organisms has become quite a simple matter.

The case that brought to our attention the necessity of doing such studies was that of a 2 year old child who was brought to the Station Hospital on Dec. 6, 1943 because of a purulent conjunctivitis of the right eye. He was taken immediately to the laboratory and a smear was made on the exudate from the conjunctiva. It showed the presence of numerous intracellular and extracellular gram negative diplococci. Because of this report and the intense conjunctivitis, with the sac full of pus, the Eye Service advised admission to the hospital for adequate therapy. The child was accordingly admitted to the Contagious Disease Service.

The history, obtained from the mother, revealed the fact that the child had coryza on December 4. On the morning of December 5 it was noticed that his right eye had become inflamed. This condition grew worse, and frank pus oozed from the conjunctiva that afternoon. His admission to the hospital was advised on the morning of December 6. Examination was completely negative except for a temperature of 99.6 F. and the presence of a purulent conjunctivitis of the right eye. Because of the laboratory report he was placed on sulfathiazole by mouth and irrigations of the conjunctival sac with boric acid solution. At the start it was necessary to irrigate the eye about every fifteen minutes to remove the exudate, but the time interval was soon increased.

The laboratory, in the meantime, had made a culture by rubbing the fresh swab of exudate on the surface of a "chocolate" agar plate, as previously described by one of us.¹ The following day the abundant growth of "oxydase positive" gram negative diplococci was washed from the chocolate agar plate and typed by the method described by Phair, Smith and Root.² The organisms were agglutinated with type I meningococcus antiserum and failed to agglutinate with types II or III meningococcus antiserum or gonococcus antiserum.

This report was telephoned to the ward on December 7, the second hospital day. The eye was much improved, and sulfathiazole therapy was continued. The contemplated search for the source of infection was, however, discontinued. The next day there was no longer any purulent discharge and the child

was discharged from the hospital. The highest recorded temperature was 99.6 F. by rectum. At no time was there any evidence of systemic infection.

COMMENT.

The finding of *Neisseria intracellularis* in acute suppurative conjunctivitis in the absence of any clinical signs of meningococcal infection of other tissues seemed to us to be unusual and to have far-reaching possibilities. We looked through three standard textbooks of ophthalmology and found that May's *Diseases of the Eye*³ does not mention the meningococci as a cause of conjunctivitis. Parsons⁴ merely states that it is sometimes found in the conjunctival sac. Duke-Elder's⁵ monumental work has much more on the subject. He mentions a catarrhal conjunctivitis as occurring as an acute metastatic phenomenon of meningococcal infection. He quotes some literature to show that it may occur without general symptoms and that Reese reported a case of meningitis which followed a conjunctival infection. He cites one report in which it caused a pseudomembranous conjunctivitis with corneal ulceration but does not mention whether or not meningitis was associated with it.

A survey of recent literature reveals that meningococcal conjunctivitis associated with infection of other tissues is not uncommon. It is, however, quite rare in the absence of such involvement. Clifton and Laird⁶ report 2 cases, in 1 of which a group I meningococcus was proved to be the etiologic agent. In the other, similar proof, cultural and serologic, is lacking, but it is assumed to be identical on the basis of its clinical similarity to the first. These authors in reviewing the literature cite only 3 other cases of meningococcal conjunctivitis in the absence of other symptoms. A fourth case is mentioned by DeBord⁷ in a man in which a group I meningococcus was isolated. It is not clear, however, whether other tissues were involved by the meningococcus.

The recent studies on meningococcus "carriers" and their control by Schoenbach⁸ and Cheeves, Breese and Upham⁹ show the widespread and common occurrence of meningococci in "normal" throats. Duke-Elder¹⁰ mentions the presence of meningococci in the conjunctivas of such carriers. These facts suggest the great possibility for infection of the eye with these organisms and indicates the fallacy of reporting gonococci from smears from acute purulent conjunctivitis without cultural and serologic confirmation. In our hands the use of the chicken serum² for such agglutination has been very satisfactory and has led to complete identification within twenty-four hours of the time that the gram negative diplococcus was grown.

The necessity for such identification is quite apparent in those cases in which there is no obvious method of spread of infection as from a urethritis, vaginitis in a child or cervicitis. Before further energy is spent in search for the contact, such identification should be undertaken.

In all the cases that have been adequately described, as well as our own, a respiratory infection was the mode of onset. While this might be a clue, it is at most a very tenuous one. It might, however, help in the type of case mentioned (no obvious source of contamination) to consider the possibility of the meningococcus as the gram negative intracellular diplococcus when it is found.

CONCLUSION

The diagnosis of meningococcal conjunctivitis should be suspected in cases with gram negative intracellular diplococci seen in smears of pus in which no obvious source of the infection is discernible.

INSULINS AND INSULIN MODIFIERS

INTRADERMAL STUDIES

ROBERT L. PAGE, M.D., AND LOUIS BAUMAN, M.D., NEW YORK

In their respective textbooks Joslin,¹ Wilder² and Duncan³ have stated that injections of protamine zinc insulin are more apt to produce cutaneous reactions than regular insulin.

During an experience of seven years we have found that globin insulin (with zinc) has only rarely been followed by cutaneous reactions. Bauman⁴ found that several patients who had severe skin reactions after injections of protamine zinc insulin obtained immediate relief when globin insulin (with zinc) was substituted. Duncan⁵ replaced protamine zinc insulin with globin insulin (with zinc) in 2 patients and noted a disappearance of the irritation of the skin. In the article published by Bailey and Marble⁶ local reactions were not encountered when globin insulin (with zinc) was used.

As the question of sensitivity to insulin is of some practical importance and because we wanted to see if the results of cutaneous tests with uncombined protamine and globin would parallel the clinical experience with the respective insulin combinations, we tested a group of 91 allergic and 81 diabetic nonallergic patients with various insulins and insulin modifiers. All of the diabetic patients had received therapeutic injections of one or more types of insulin.

SOLUTIONS EMPLOYED

Protamine.—The same product as is used in the preparation of protamine zinc insulin was used. It is obtained from the sperm of the fish belonging to the salmonidae family.

Total Globin (beef).—Though globin contains considerable arginin and histidine, it is a neutral protein more like an albumin than a protamine or histone (Bauman⁷). Total globin was prepared from beef hemoglobin according to the method of Anson and Mirsky.⁸

Native Globin Beef.—Native globin was prepared from total globin (beef) by neutralization of its solution with alkali. The matured globin precipitates, leaving the native globin in solution. Native globin (beef) is used in the preparation of globin insulin (with zinc) (Reiner, Searle and Lang⁹).

Globin (human).—Total globin from human hemoglobin was prepared according to the aforementioned method. Two sources were used and are designated in these studies as globin (human) A and B.

Insulin Beef (market).—Regular insulin, stated to be from beef pancreas, was purchased on the market. It was diluted so that there was 0.01 mg. of nitrogen per cubic centimeter. The average zinc content of regular insulin U-40 varies over a range of about 0.041 to 0.049 mg. per hundred cubic centimeters.¹⁰ This is approximately $\frac{1}{175}$ the amount of zinc present in protamine zinc insulin.

Crystalline Insulin.—We were especially desirous of obtaining an insulin that was as free from zinc as possible; hence the following process was employed. "Wellcome" brand of crystalline insulin was recrystallized once in phosphate buffer with zinc according to Scott and Fisher's method¹¹ and once

from ammonium acetate without the addition of zinc. Then it was dissolved in hydrochloric acid and dialyzed for six days; it was then precipitated at the isoelectric precipitation point and the precipitate dissolved again in hydrochloric acid and dialyzed for two days and finally electrodyalyzed until completely precipitated. This was then dissolved in sufficient hydrochloric acid to form a clear solution. Determinations of zinc were carried out according to the method described by the Council on Pharmacy and Chemistry of the American Medical Association¹² and the results were negative.

Insulin (p-azobenzyltrimethylammonium chloride).¹³—This insulin compound was prepared from Wellcome brand crystalline insulin according to the method described by Reiner and

TABLE 1.—Results of Intradermal Studies on Nondiabetic and on Diabetic Patients Using Various Test Solutions*

Test Solution (0.01 Mg. N/Cc. 0.02 Cc. Intradermally)	Nondiabetic Patients (91 Tested) Positive Reactions, %	Diabetic Patients	
		Patients Tested, No.	Positive Reactions, %
Protamine	48.3	81	18.5
Native globin (beef) ..	2.1	81	2.4

Zinc Chloride Control.—This solution contained 0.5 mg. of zinc chloride per cubic centimeter, so that the amount given as a test dose (0.02 cc.) contained 0.0048 mg. (4.8 micrograms) of zinc. This amount of zinc would correspond to the zinc present in 2.4 units of protamine zinc insulin (80 units of protamine zinc insulin contains approximately 0.15 mg. of zinc).

COMMENT

The results of this study are presented in the accompanying tables. Of the preparations tested, zinc chloride, beef insulin and protamine were the most irritating. The incidence of sensitivity to protamine was much greater in the allergic patients. In this group reactions to protamine were twenty-four times more frequent than to globin. In the nonallergic diabetic group the number of reactions to protamine was less, possibly because some of these persons had received injections of protamine zinc insulin and were desensitized. However, here too the ratio of protamine reactions to globin reactions was more than 7.5 to 1.

These results are in keeping with those of the toxicity studies of Reiner, deBeer and Green,¹⁶ who found that globin was devoid of toxicity when injected into animals or tested on tissues or monocellular organisms, whereas protamine was toxic both to tissues and to trypanosomes. The globin and protamine sensitization experiments of Reiner, Searle and Lang indicated that globin and globin insulin (with zinc) were only weakly antigenic, and this observation is confirmed by our experience with human diabetic patients.

The irritating effect of zinc chloride was to be expected. In the diabetic group the frequency of reactions to beef insulin was five times greater than to the purified substance. We are at a loss to explain this result.

CONCLUSIONS

1. Cutaneous reactions to protamine are more frequent than to globin in allergic and in nonallergic patients.
2. Diabetic patients receiving injections of protamine zinc insulin become desensitized to protamine.
3. Diabetic patients to whom globin insulin (with zinc) had been administered daily for about five years were not sensitive to globin.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary.

ALLERGENIC PREPARATIONS (See New and Non-official Remedies, 1943, p. 29).

The following dosage forms have been accepted.

REICHEL LABORATORIES, INC., KIMBERTON, PA.

Protein Extracts Diagnostic: These extracts for the diagnosis of protein sensitivity by the intracutaneous method are supplied in 1 cc. size cartridge ("Tubex") vials containing sufficient protein material of appropriate dilution for twenty to thirty tests. The test sets are accompanied by a suitable cartridge syringe, sterile needles and three cartridge vials each of epinephrine hydrochloride solution, buffered saline solution and distilled water. After injection of each extract the needle should be flushed with distilled water to avoid contamination with the extract used previously.

Extracts marketed in dilution representing 0.05 mg. of nitrogen per cubic centimeter:

Apple,³ Apricot,³ Banana,³ Blackberry,³ Cantaloupe,³ Cherry,³ Dates,³ Fig,³ Grape,³ Grapefruit,³ Lemon,³ Orange,³ Peach,³ Pear,³ Pineapple,³ Plum,³ Prune,³ Raspberry,³ Strawberry,³ Watermelon,³ Beef,³ Chicken,³ Mutton,³ Pork,³ Artichoke,³ Asparagus,³ Beets,³ Broccoli,³ Cabbage,³ Carrot,³ Cauliflower,³ Celery,³ Cucumber,³ Endive,³ Garlic,³ Green Pea,³

Leeks,³ Lentil,³ Lettuce,³ Mushroom,³ Olive,³ Onion,³ Parsley,³ Pepper (Green),³ Potato (Sweet),³ Potato (White),³ Pumpkin,³ Radish,³ Rhubarb,³ Spinach,³ Squash,³ Tomato,³ Turnip,³ Watercress.³

Extracts marketed in dilutions representing 0.01 mg. of nitrogen per cubic centimeter:

Goat Hair,⁵ Wool,⁵ Chicken Feathers,⁵ Duck Feathers,⁵ Goose Feathers,⁵ Alfalfa (Hay),⁴ Rice Powder,⁴ Coffee,⁴ Tea,⁴ Bran,⁴ Corn (Sweet),⁴ Oats,⁴ Rice,⁴ Rye,⁴ Wheat,⁴ Milk (Cheeses),⁴ Lactalbumin,⁶ Bay Leaves,⁴ Cinnamon,⁴ Clove,⁴ Ginger,⁴ Nutmeg,⁴ Thyme,⁴ Hops,⁴ Kidney Bean.⁴

Extracts marketed in dilutions representing 0.005 mg. of nitrogen per cubic centimeter:

Cocoa (Chocolate),⁴ Lima Bean,⁴ Navy Bean,⁴ Pea,⁴ Soy Bean,⁴ String Bean,⁴ Brazil Nut,⁴ Cashew Nut,⁴ Chestnut,⁴ Hazel Nut,⁴ Hickory Nut,⁴ Pecan,⁴ Pistachio.⁴

Extracts marketed in dilutions representing 0.001 mg. of nitrogen per cubic centimeter:

Camel Hair,⁵ Cat Hair,⁵ Cow Hair,⁵ Dog Hair,⁵ Horse Hair,⁵ Horse Hair,⁵ Rabbit Hair,⁵ Silk,⁵ Cotton Seed,⁴ Kapok Seed,⁴ Orris Root,⁴ Pyrethrum,⁴ Tobacco,⁴ Flaxseed,⁴ Barley,⁴ Almond,⁴ Coconut,⁴ Peanut,⁴ Walnut (English),⁴ Bass,⁴ Bluefish,⁴ Carp,⁴ Clam,⁴ Cod,⁴ Crab,⁴ Flounder,⁴ Haddock,⁴ Halibut,⁴ Herring,⁴ Lobster,⁴ Mackerel,⁴ Oyster,⁴ Perch,⁴ Pike,⁴ Salmon,⁴ Sardine,⁴ Scallop,⁴ Shad,⁴ Shrimp,⁴ Smelt,⁴ Sole,⁴ Trout,⁴ Tuna,⁴ Anise Seed,⁴ Caraway Seed,⁴ Yeast,⁴ Orchard Grass,⁴ Sweet Vernal Grass,⁴ June Grass,⁴ Sagebrush,⁴ Wormwood,⁴ False Ragweed,⁴ Western Ragweed,⁴ Timothy,⁴ Red Top,⁴ Plantain,⁴ Ragweed,⁴ Giant Ragweed,⁴ Cocklebur,⁴ Bermuda Grass,⁴ Johnson Grass,⁴ Russian Thistle,⁴ Ash (White),⁴ Ash (Oregon),⁴ Alder,⁴ Beech,⁴ Birch,⁴ Elm,⁴ Hickory,⁴ Maple,⁴ Oak,⁴ Poplar,⁴ Sycamore,⁴ Walnut,⁴ Beaver,⁵ Caracul,⁵ Ermine,⁵ Fox,⁵ Lamb (Black),⁵ Lamb (Persian),⁵ Leopard,⁵ Mink,⁵ Muskrat,⁵ Nutria,⁵ Rabbit,⁵ Raccoon,⁵ Skunk,⁵ Seal,⁵ Squirrel,⁵ Weasel.⁵

Extracts marketed in dilutions representing 0.0005 mg. of nitrogen per cubic centimeter:

Egg (Chicken),⁷ Mustard,⁴ Glue (Fish).¹⁰

Extract marketed in dilutions of 1-10:

House Dust.⁸

Extract marketed in dilutions of 1-100:

Horse Serum.⁹

Protein extracts diagnostic Reichel are prepared from the various substances by extraction with a slightly alkaline, buffered saline solution composed of sodium chloride, 0.5 per cent, sodium bicarbonate, 0.275 per cent and phenol 0.4 per cent, in distilled water. Carbon dioxide is then bubbled into the extracts until they become colorless when tested to phenolphthalein. The products are standardized on the basis of their nitrogen content per unit volume (Kjeldahl method). Certain products, namely house dust and horse serum, not lending themselves to such standardization are therefore marketed in dilutions of 1-10 and 1-100 respectively.

Extracts marked 1 are prepared by the following method: The juices are squeezed and separated from pulp by filtration. The *pH* is adjusted to 7.4 with sodium carbonate, diluted with buffered alkaline saline solution, filtered, standardized and diluted to appropriate strength.

Extracts marked 2 are prepared by the following method: The crude material is ground as fine as possible. Alkaline buffered solution is added to the pulp and allowed to extract under toluene for from one to two days at room temperature. After the toluene has been removed in a separator the extract is filtered, standardized and diluted to appropriate strength.

Extracts marked 3 are prepared by the following method: After the removal of all fat and tendons, the muscle fibers are then ground as fine as possible. The ground material is washed with warm (50 C.) toluene until entirely free of fats. The toluene washings are discarded and the ground meats are extracted under toluene with alkaline buffered saline solution at room temperature for from one to two days. The toluene is then removed in a separator and the extract is filtered, standardized and diluted to appropriate strength.

Extracts marked 4 are prepared by the following method: The materials are ground as fine as possible, the powder or flour is washed with ether and toluene until the washings are clear and colorless. The washings are discarded and the residue is dried. The dried residue is extracted with alkaline buffered saline solution under toluene at room temperature for from one to two days. The extract is filtered through a Buchner funnel and the toluene removed in a separator. The extract is filtered, standardized and diluted to appropriate strength.

Extracts marked 5 are prepared by the following method: The materials are washed with ether and toluene, dried and extracted under toluene for from one to two days at room temperature. The extract is cleared of toluene in a separator, filtered, standardized and diluted to appropriate strength.

Lactalbumin, marked 6, is prepared by the following method: The casein is precipitated with rennin and the lactalbumin, after neutralization with sodium bicarbonate, is precipitated from the resulting whey with acetone. The lactalbumin is then extracted with alkaline buffered saline solution, filtered, standardized and diluted to appropriate strength.

Egg (Chicken), marked 7, is prepared by the following method: The white is separated from the yolk and diluted with alkaline buffered saline solution, filtered, standardized and diluted to appropriate strength.

House Dust, marked 8, is prepared by the following method: The dust is defatted with ether and toluene, dried, extracted with alkaline buffered saline solution, dialyzed, filtered and diluted to appropriate strength.

Horse Serum, marked 9, is prepared by the following method: Normal Horse Serum is treated with phenol, so that the final concentration of phenol is 0.4 per cent. It is then diluted to proper strength with alkaline buffered saline solution.

Glue (Fish), marked 10, is prepared by the following method: The glue is diluted in alkaline buffered saline solution, standardized and diluted to appropriate strength with alkaline buffered saline solution.

WHAT THE PEOPLE THINK ABOUT
MEDICINE AND MEDICAL
SERVICE

In July 1943 the National Physicians Committee employed the largest opinion research group in this country to make a comprehensive study of the people's opinion about medical care. The results of that study have just been made available. In making this survey the National Physicians Committee has rendered a distinguished service to American medicine. The report should be of great help to medical leaders by pointing the way in planning for the extension of medical service. The report indicates the necessity for more education of the public regarding the issues involved in proposals for changing the nature of medical service. When people understand the issues, an overwhelming majority are unqualifiedly opposed to any such proposals as the Wagner-Murray-Dingell bill, which would establish federal control of medical practice. Even though the people sense the need for the extension of facilities designed to meet the costs of unusual or prolonged illness, only a small minority, as shown by this report, believe that compulsory sickness insurance would provide a satisfactory solution to the problem.

Many of the questions in this research concerned the personal experiences of the people with medical care as now provided in the United States. The replies, in great majority, indicated that the people are deeply conscious of the value of individualized service in the effectiveness of medical care, that they want complete freedom of choice in time of illness and that they believe choice would be limited and restricted by administration of medical care under the auspices of the federal government.

Out of this report came the conviction that many persons find difficulty in meeting bills for unusual or prolonged illness and desire to participate in plans or methods for insurance against the hazards of emergency illness. Already great numbers of people are familiar with the various prepayment plans for medical service

available throughout the country. The investigations extended into many communities in which such plans are operating and covered the experiences of the participants. To summarize the many questions asked on this phase of the report: Persons who participate in prepayment plans approve them; in every instance such persons believe they are better off than their neighbors who have no such opportunity; the doctors in areas where such plans are in operation believe that the people are better off because of the operation of the plan. More than 50 per cent of the doctors in such areas stated that it would be a good thing if all industries would operate prepayment medical and hospital service plans for their employees.

In a special survey, paralleling the study of medical service, opinion was sought concerning the American Medical Association. More than three fourths of the people who were questioned had heard of the American Medical Association, and about half of these defined its purposes with reasonable accuracy. In general, those who had heard of the American Medical Association expressed approval. The inquiry about the American Medical Association was made in the survey to determine the extent to which mention of the public education activities of the medical profession would tend to have a favorable or unfavorable influence on public thinking. The best evidence that the American Medical Association was considered a "favorable symbol" was the fact that most people think of the purposes of the American Medical Association as being "to sponsor new medical technics; to keep the standards of medical practice high; to give endorsement to acceptable medical products." Moreover, less than one tenth of the people interviewed thought of the American Medical Association as a "union" of physicians or as a "trust" or as being otherwise primarily a self-interested body.

The report of this survey, which is available through the National Physicians Committee, should do much to counteract the irresponsible and sometimes malicious criticisms that have been expressed recently within and without the medical profession. The scope and the accuracy of this survey cannot be questioned. The results are a challenge to medical leadership. Only through enlightened medical leadership can medical service and medical science continue to evolve in the United States beyond the high point that they have now attained. The advancement of medical science and of medical education is fundamental to the quality of medical service. Some of the proposals that have been made to federalize medical service, coming from outside the medical profession, would subsidize education and research. From within have come proposals to "unionize" or "commercialize" medical service. The professional status of medical care and medical science must be maintained. The economic factors involved in

securing wider distribution of medical service must be studied and the widest possible application of these services secured. But even the economics of medical service must always be dependent on the science, the art and the practice of medicine.

HYPERPLASIA OF THE PROSTATE

A morphologic study by Moore¹ of so-called benign hypertrophy of the prostate emphasizes that the terms "hypertrophied prostate" and "prostatectomy" do not convey the same idea to the specialist in the urologic field that they do to the general practitioner. The urologist has for some time been aware that the prostate that causes obstruction to urinary flow need not be hypertrophied; the operation he performs for the relief of urinary obstruction is not prostatectomy. The anatomic changes concerned, Moore points out, are nodular hyperplasia and not hypertrophy of the gland. Nodular hyperplasia, therefore, would be a preferable term. The nodules develop from the periurethral glands and also from some point in the prostate itself. Moore's histologic studies showed that the earliest nodules may be demonstrated in acini of the middle and lateral lobes of the prostate about the collicular and subtrigonal periurethral glands, all structures which empty cephalad to the verumontanum. In only 1 instance of 700 prostates examined by him was a nodule demonstrated in a posterior lobe which empties caudal to this point. Moore concludes from these observations that the stroma of the prostate cephalad to the verumontanum reacts to different stimuli or to a greater extent to the same stimuli than does that caudal to the verumontanum. Possibly also the posterior lobe of the prostate is biologically different from the other lobes. Nodules composed only of smooth muscle are not distinctive but represent a variant in which the stromal hyperplasia does not include glands. Nodular hyperplasia is associated with development of masses of lymphoid tissue, an appearance frequently mistaken for an inflammatory infiltration of lymphocytes. Inflammation may occur in the prostate with hyperplasia, but it is not the cause of the disease. The uninvolved part of the prostate shows atrophy and atypical hyperplasia, the histologic evidence of irregular or abnormal stimulation.

As the nodules increase in size, compression of the posterior lobe and of the peripheral portion of the lateral lobes occurs, so that in extreme examples they may not exceed 1 mm. in thickness. This compressed tissue, which in reality is the true prostate gland, has been called the surgical capsule. It is not the same as the anatomic capsule. Microscopically the changes

are characteristic and analogous to those of compression atrophy in other glandular organs. This compression atrophy should not be confused with senile atrophy of the posterior lobe that occurs in the absence of so-called benign hypertrophy.

Moore stresses that suprapubic prostatectomy is not in any sense prostatectomy. The operation actually is lobectomy, that is, a removal of the newly formed nodules; the prostate itself is not removed. Moore considers it highly probable that the urinary obstruction in these cases is a physiologic mechanism dependent on the function of the internal sphincter, possibly on spasm. He believes that it is possible that the beneficial results of prostatectomy are the result of destruction of the internal sphincter rather than of the removal of 50 or 100 grams of tissue. The success of the transurethral operation at the bladder neck lends some support to this hypothesis.

BASAL TEMPERATURE AND DATE OF OVULATION

As early as 1904 van de Velde pointed out the existence of variations in body temperature during phases of the menstrual cycle. A number of clinical investigations since then have confirmed his observation. Rubenstein¹ correlated a study of vaginal smears with a study of basal temperatures and found that during the phase of follicle development the basal rectal temperature tends to drop progressively. The low point in the temperature curve is reached when the follicle matures. Coitus at this time is therefore most likely to result in conception. The beginning progesterone production which occurs before ovulation suffices to counteract in part the temperature depressing action of estrone and therefore to cause an initial temperature rise beginning a few hours before ovulation. The temperature rise continues after ovulation and should exceed 0.5 degree F. in the first twenty-four hours after ovulation and 1 degree F. the first week after ovulation. As soon as the corpus luteum has regressed (a few days premenstrually) new follicles begin to develop. Estrone production begins again, although at a low level. Since there is now no functional corpus luteum, the temperature depressing action of estrone is again apparent and the temperature begins to go down. The drop continues through the preovulative phase of the next cycle. In the event of pregnancy, corpus luteum function persists and the temperature rise of the post-ovulative phase is maintained. If the temperature curves of a number of previous cycles are available, it is sometimes possible to detect pregnancy before the period is missed, since the temperature remains high.

1. Moore, Robert A.: Benign Hypertrophy of the Prostate, *J. Urol.* 50: 680 (Dec.) 1943.

1. Rubenstein, Boris D.: The Vaginal Smear, Basal Body Temperature Technique and Its Application to the Study of Functional States in Women, *Endocrinology* 27: 843 (Dec.) 1940.

Greulich and Morris² performed laparotomies on 14 women whose temperature records were kept daily for several successive menstrual cycles. Eight of the 14 women were found to have ovulated during the current cycle and 6 showed no indication of recent ovulation. In each of the former the temperature curve showed a characteristic rise of temperature preceding the ovulation. In 5 of the 6 who failed to ovulate, no such temperature rise occurred. A study of basal temperatures in 35 women by Williams³ showed that during the first half of the cycle an average temperature level of about 98 F. is usually maintained, often followed by an abrupt drop of 0.3 to 0.4 degree and then a shift to a higher temperature level, which continues at about 98.5 F. until one to three days before the onset of the next menstruation. The time of the shift from the low to the high temperature plateau marks the time of ovulation. According to Williams, this general temperature pattern is quite constant in normally ovulating women but varies greatly with pathologic ovulation.

In an article in this issue of *THE JOURNAL* Tompkins⁴ advocates a wider clinical application of the method of detection of the date of ovulation through basal temperature graphs. The method is based on the apparently well established observation that there is a typical temperature curve during the menstrual cycle. The temperature is relatively low during the first part of the month, drops to a minimum about the time at which ovulation occurs and rises definitely thereafter to a relatively high level, which is maintained until the next menses, when the temperature drops abruptly. Such temperature fluctuations are not found before the menarche, after the menopause or in men. If conception occurs, the temperature will remain at the high postovulation level. Tompkins has developed a special form, printed on grid paper, for the recording of daily basal temperatures. Tompkins believes that with the aid of these graphs it will be possible frequently to indicate the date of ovulation. In his experience these graphs have been useful in suggesting to childless couples the time of maximum fertility, in determining the date for endometrial biopsies and in setting the date for artificial insemination in 2 cases, both of which were successful after previous failures. The graphs may also be used to detect the "unsafe period" for those who do not use contraceptive measures. In determining the date of ovulation by the consideration of the basal temperatures, one should remember that such determinations would be correct only in the absence of any infection.

AMERICAN BAR ASSOCIATION CONDEMNS SOCIALIZED MEDICINE

Elsewhere in this issue (page 716) appears a report adopted Feb. 28, 1944 by the House of Delegates of the American Bar Association relative to the Wagner-Murray-Dingell bill, generally called the "socialized medicine bill." The report criticizes the proposed legislation because it is "prepared in a form which has become popular in the past ten years, being replete with involvement, cross references, new terminology, percentages and other confusing matters," so that the chapter on socialized medicine leaves the reader in utter confusion as to its meaning. The distinguished lawyers who prepared this statement point out that "no one can estimate how much tax money is involved or how many people are covered" from the face of the bill. Since, however, the bill would propose to include every individual worker and since every family in the United States has at least one and one-half employed working members, the coverage would include practically every family in the United States.

The statements made by Senator Wagner in introducing this measure are analyzed and at least twelve are pilloried as incorrect and misleading.

A fourth section of the report emphasizes the high quality of medical service prevailing in the United States today and points out that the indigent who are most in need of medical care would not be covered by this measure. "The Wagner-Murray-Dingell bill," says this statement, "would inevitably produce communistic medicine in the United States and would put all the people in a medical straitjacket under the supervision of the federal government for an alleged service which the vast majority either do not require or are able to provide for themselves."

Finally the report emphasizes that there are being developed in this country and under our system of private enterprise many plans for providing adequate medical care without paying the price of socialized medicine. At a previous session the House of Delegates of the American Bar Association stated its opposition "to any legislation, decree or mandate that subjects the practice of medicine to federal control and regulation beyond that presently imposed under the American system of free enterprise."

As a reason for its entrance into consideration of the Wagner-Murray-Dingell bill the House of Delegates of the American Bar Association explains that its organization is limited to an expression of opinion and judgment with respect to those fields which relate to the administration of justice and which directly affect the safeguards and protection of the rights and liberties of the citizens of this country. When, therefore, under the pretext of the general welfare, legislation is proposed in Congress which either inadvertently or with deliberate

2. Greulich, William Walter, and Morris, Edward S.: An Attempt to Determine the Value of Morning Rectal Temperature as an Indication of Ovulation in Women, *Anat. Rec.* 79: 27 (March 25) 1941.

4. Tompkins, Pendleton: The Use of Basal Temperature Graphs in Determining the Date of Ovulation, this issue, p. 698.

subtlety constitutes a direct attack on the rights and liberties of the citizens of this country, it becomes the duty of the American Bar Association actively to voice its objections. The six objections listed specifically include the extent to which the measure depreciates local self government: a condemnation of the authority vested in the Surgeon General of the United States Public Health Service by S. 1161 which would give him the power arbitrarily to make rules and regulations having the force and effect of law; a condemnation of the procedure by which physicians, hospitals and individual citizens would be made to serve the purposes of a federal agency; the failure of the bill to safeguard the rights of patients, citizens, hospitals or doctors, which might be denied by the arbitrary or capricious action of one man; the failure of the bill to provide for any appeal from the action of the Surgeon General; and, finally, the severe condemnation of the vicious system whereby administration officials judge without court review the actions of their subordinates in carrying out orders which might be issued to them.

The final paragraph of this report of the American Bar Association merits quotation and requotation as a fundamental appeal to the citizens of the United States to protect the Constitution. This statement says:

The Constitution of the United States is designed to protect the citizens of this republic in the exercise of the rights of free men. The provisions of that instrument can be rendered impotent when our citizens, for the sake of an apparent immediate benefit, surrender to their government such direct control over their lives that government, by imposing a constant fear upon them of having those benefits withheld or withdrawn, can compel from them obedience and subservience to its dictates.

PATHOLOGIC ANATOMY AT WAR

Elsewhere in this issue (p. 710) an article on the Army Medical Museum explains the organization of pathologic anatomy in the Medical Department of the U. S. Army. The startling accomplishments of surgery, medicine, physiology, bacteriology and epidemiology as they partake in the war effort tend to obscure the significant part played by pathologic anatomy. In man, and in animals with natural or experimentally induced disorders, the final identification of disease, indispensable in investigation, depends on pathologic anatomy. Through the medium of autopsies and surgical specimens, pathologic anatomy serves the Army in its usual unpretentious manner. The organization now operating in the Army is such that careful examinations can be made in the field; central facilities provide for skilled controls and permanent files. Surgeons are aided in their operative work, internists in their investigation of patients and all medical officers in diagnosis, treatment and prevention, not only of internal diseases, but of injuries on land, on sea and in the air. Recognition of

these evident facts should lead to the appropriate placing of pathologic anatomy in all phases of medical work in the services, in the setup of medical administration and in the hospitals and other installations here and abroad. Pathologic anatomy is very much "in" for the duration and beyond.

INTERNSHIPS AND RESIDENCIES FOR LATIN AMERICAN PHYSICIANS

Elsewhere in this issue is an announcement of the decision by the Procurement and Assignment Service that "graduates of Latin American schools currently serving as interns or residents would not be counted in hospital quotas." This ruling should do much to facilitate the hospital training of Latin American physicians, who are coming to this country in increasing numbers for internship and residency training. Until recently the educational and professional ties of many Latin American countries were firmer with European centers of medicine than with the institutions in the United States. The decline of learning and science, including medical education, in Europe during the war will tend to increase the importance of the United States as a center for advanced training for years after the war. Schools and institutions here have escaped not only the physical destruction of war but the even more damaging effects of the intellectually sterile philosophies of the fascist countries. After the war we may expect to be host to many more Latin American physicians, who will turn to the United States rather than to Europe. This tendency deserves the full support of the profession in this country, which will share in a mutually beneficial exchange of ideas and the cementing of lasting inter-American friendships. The Procurement and Assignment Service is to be congratulated for its wisdom in taking an important step in this direction. Medical schools and hospitals will doubtless encourage the postgraduate education of Latin American physicians.

CATIONIC SOAP

The term cationic soap is applied to synthetic detergents which are excellent germicides and are also effective skin cleansers when employed in aqueous solutions at about 1 per cent concentration. In the course of studies on the effectiveness of these agents for rapid degermination of the hands, Miller and his colleagues¹ discovered that they deposit a nonperceptible film on the skin. This film retains bacteria underneath it and is resistant to mechanical trauma; whereas the outer surface exerts a strong germicidal action, the inner surface of the film has a low bactericidal power. These observations introduce a further complication into the evaluation of products of this type.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

ARMY

ARMY MEDICAL MUSEUM

Army Institute of Pathology

Howard T. Karsner, M.D.

CLEVELAND

An understanding of the part which pathology plays in the medical service of the Army depends in large part on a realization of what goes on in the Army Medical Museum. This remarkable institution was established in 1862 by order of Surg. Gen. William A. Hammond, when he directed medical officers to send to his office morbid anatomic specimens illustrating wounds and the effects of projectiles. Seven months later, 1,349 specimens had been collected. Situated first in the Surgeon General's Office, a separate building was required within a year. Ford's Theater was closed after the assassination of President Lincoln but was subsequently altered by order of Congress for the housing of the museum. Money for the present building was appropriated in 1885 and construction completed in 1887, or fifty-seven years ago. The Army Medical Library, which was established by Surgeon General Lovell in 1835, has shared these quarters from the beginning.

Visitors from Europe have repeatedly praised the museum, and in 1870 Berenger-Féraud said that the United States had done as much in five years as had all Europe in a century and that our museum contained more specimens than all the pathologic anatomic museums of Europe combined. It remains the only medical museum maintained by the United States government.

The present communication is not concerned principally with the function as a museum, even though by 1937 there were 150,000 specimens and 45,000 photographs. Nor is there any need to discuss the education of the public in matters of preventive medicine and hygiene through the medium of exhibits, which occupy 15,200 square feet of floor space. In passing, however, it may be mentioned that there are now well over 100,000 visitors a year.

In his book "Victories of Army Medicine," Brigadier General Hume¹ says that Surgeon General Hammond had in mind the study of specimens collected in order to "lead to reduction in mortality." This has been done by investigation and by teaching. Hume speaks of three great institutions, the Army Medical Library, the Army Medical Museum and the Army Medical School. These have been closely associated, and the museum staff has been responsible for teaching pathology in the school. Teaching of various other groups will be mentioned later.

The purposes of the museum have been expanded so that it is now authorized to use as a subtitle Army Institute of Pathology. As a matter of fact, the new subtitle gives a clearer indication of its present activities than the original designation. Army Regulation 40-410, issued Aug. 3, 1942, states that "the primary professional function of the Army Medical Museum is to furnish a central service for tissue pathology." This central laboratory has three major aims, which are (a) diagnosis and review of pathologic material, (b) instruction and (c) research.

The arrangements for diagnosis and review of pathologic material have been found to be highly effective. The professional staff of the museum now includes a group of active pathologists well trained in general pathology and certain of its

special fields as well as pathologists especially competent in dental and in veterinary medicine. Because of obvious limitations, fully trained pathologists cannot be provided for every army hospital. To meet this situation, seventeen histopathologic centers have been established in the United States and several central laboratory units have been sent overseas, all staffed by trained personnel. Through these channels all autopsies are reported to the institute laboratories, including protocols, clinical abstracts, photographs, x-ray films, microscopic sections, paraffin or tissue blocks and, when advisable, whole organs. All places where autopsies are to be performed are supplied with a directive of technic prepared at the request of the Surgeon General by a Conference Group on Pathology of the National Research Council. Surgical specimens are similarly routed, especially all tumors, but the histopathologic centers are expected to "screen out" material not of sufficient importance to be sent in for review. Reports are sent to the referring laboratories and also placed in the permanent files of the museum. Thus any medical man is assured that study of cases at autopsy is not restricted by field conditions, and any surgeon knows that his material will be examined by groups of well qualified pathologists. If the surgeon is in a hurry, his specimen can be sent by air mail and he receives a report by radiograph.

Army Regulation 40-410 directs that the material be made available "for teaching purposes at Medical Department schools, other schools devoted to military education, and for recognized medical, dental and veterinary schools." The teaching function is exercised in various ways. Teaching at the Army Medical School has been mentioned. For a time, officers from army laboratories and those about to assume such duties were assigned to the museum for temporary duty in order to become familiar with the museum and its work. Certain officers have been assigned to develop various special fields, such as neuropathology and dermal pathology. Of great importance is the preparation and distribution of "study sets." These are widely circulated among army hospitals and give the officers exceptional opportunity to study various lesions. The sets, each numbering from 25 to 50 microscopic sections, cover such subjects as epidemic hepatitis, periarteritis nodosa, nevi and dermal cancer, interstitial pneumonitis, intracranial tumors, diseases of the thyroid, diseases of the lymph nodes and lesions of the distal parts of the nephrons. The list is constantly being enlarged.

The clinicopathologic conference is also used as a teaching method. The museum furnishes material for these exercises, including clinical records, autopsy protocols, microscopic sections, lantern slides, epicrises and bibliographies. These are readily available to army medical installations.

Material on tropical diseases is provided for the Army and to civilian schools. For this purpose tissue blocks, microscopic sections and lantern slides, and material for clinicopathologic conferences can be procured on application to the curator. This activity, supported by the John and Mary R. Markle Fund, is of far reaching importance in present day instruction. With the aid of the Josiah Macy Jr. Foundation, lantern slides have been prepared and distributed for the use of civilian pathologists who participate in the remarkable program of postgraduate instruction in the hospitals of the Army Air Forces.

In line with its educational program, the museum maintains several registries of pathology. Army Regulation 40-410 authorizes the museum "to act as custodian for the National Research Council of the American Registry of Pathology." By arrangement with various special societies, the museum receives

1. Hume, E. E.: *Victories of Army Medicine: Scientific Accomplishments of the Medical Department of the United States Army*, Philadelphia, J. B. Lippincott Company, 1943.

specimens for study both individually and collectively. Accompanying the specimens are notes on clinical features, roentgenograms and so on. The registries vary greatly in number of accessions, but it is noteworthy that there are on file approximately 2,000 cases of ocular melanoma and 4,000 tumors of the bladder and that about 125 human eyes are received each month. These registries now include tumors of the lymphatic apparatus, ophthalmic pathology, genitourinary pathology, dermal pathology, otolaryngic pathology, orthopedic pathology, gynecopathology, oral and dental pathology and tumors of the brain, the breast, the endocrines and bone. From the specimens collected, study sets comprising from 25 to 100 microscopic preparations are lent to society members and others. In addition there are exceedingly valuable atlases, illustrated by photomicrographs which are accompanied by clinical and descriptive data. These can be purchased at cost of manufacture. Started when Col. G. R. Callender was curator, the registries of pathology have increased in number and comprehensiveness and have assumed great importance under the direction of the present curator, Col. J. E. Ash.

Army Regulation 40-410 orders the conduct of "investigations and research on the accessions" and the arrangement of material so "that it will be available for reference and study by other properly qualified investigators." The staff of the museum has followed this order with keen interest. The investigations are not merely academic research projects but in large part have immediate application. The studies of epidemic hepatitis, which seemed to follow vaccination against yellow fever, showed conclusively that our troops had not contracted yellow fever as a result of vaccination. The studies of blast injuries, here and elsewhere, have determined methods of protection. Significant also are the examinations of material from cases of burns, crush syndrome, transfusion reactions, blackwater fever and the like. Both from the point of view of diagnosis and also research, attention is being given to the occurrence of tumors, malignant and benign, especially of the skin and the central nervous system, to disease of the coronary arteries and to other disorders usually thought to belong to a different age group from that active in military operations. Perhaps of less direct application, but nonetheless of vast importance, are investigations now being conducted of such conditions as primary atypical pneumonia, viral infections of the central nervous system, tropical diseases, lesions of the lymph nodes, meningitis, periarteritis nodosa, non-tuberculous destructive disease of the adrenals, tumors of the jaw and other bones, tumors within the eye and epibulbar tumors, and effects of high altitude on the ear. The list is too long to permit mention of all the conditions under study.

The photographic section has operated since 1867. It has gradually been extended and improved so that now the gross photographs and photomicrographs, both black and white and in color, are the best that can be produced. In addition, a center for medical photography, under the direction of a skilled and experienced professional, guides the work in the whole medical service of the Army, cooperates with the Signal Corps and has sent several trained units overseas. In addition to drawings and paintings, some of which date back to the Civil War, plastic art is represented by many models and moulages. With this background, a department has been established under the direction of a distinguished sculptor, in which are made latex models of wounds and other injuries. The realistic pliable plaques can be attached to extremities and on the body, so that training in the Medical Field Service School and elsewhere becomes intensely practical.

Under the authority of the Surgeon General, the museum has instituted its system of resident consultants. Civilian pathologists, especially those with established reputations in certain lines of teaching and research, take up residence in Washington for two or three weeks, during which time they are in constant daily attendance at the museum. The officers bring to them problems of pathologic diagnosis, refer certain aspects of investigations, look to them for suggestions as to further studies and generally pump them dry. In return, the consultant sees the work of an enthusiastic, energetic group of medical officers devoted to the service of the nation and of science. He sees a pathologic material which in volume, variety and current interest cannot be equaled in any other laboratory in this country and probably not in any other institution the world over.

The place is as active as the proverbial beehive, but without the physical excellence of the hive. The building is now so old as to be unsuited to its manifold purposes. Equipment is good but not ideal. Facilities of one kind or another are deficient in many respects, such as elevators, toilets and lavatories. Hazards due to fire and water have not been accurately assessed, but they exist. In spite of these handicaps, work of high order is carried on by a loyal group of medical and other officers, including regulars and those commissioned from civil life, and lay associates. It is to be urged that construction of a new building will not be delayed any longer than is absolutely necessary.

This Army Institute of Pathology goes far beyond the scope of a museum. I speak as one having authority because I am one of those who have had the esteemed privilege of being a resident consultant.

2085 Adelbert Road.

TRAINING OF NEWLY COMMISSIONED MEDICAL CORPS OFFICERS WHO ARE RECENTLY GRADU- ATED INTERNS

Many newly commissioned medical corps officers who have recently completed a nine months internship and the basic course for medical department officers are being attached to named general hospitals for the completion of their professional training, according to Army Service Forces Circular No. 47, dated Feb. 12, 1944. While attached to these general hospitals they will be given "on the job" training as understudies in active medical and surgical wards and in clinics. Duty assignment on surgical and medical services will be rotated at least once every three weeks. It is contemplated that immediately following this training in a named general hospital these officers will be assigned as medical and surgical ward officers, as laboratory officers and as medical officers with tactical units.

Subjects which should be particularly emphasized on ward rounds and in clinics include attention to and care of the seriously ill; use of penicillin in both surgical and medical cases; use of sulfonamides in both surgical and medical cases; treatment of venereal diseases; general principles of wound treatment, including débridement, control of pain, prevention and treatment of shock; treatment of fractures and other orthopedic conditions, including splints and splinting, use of plaster of paris bandages, Tobruk splints and the care and handling of back injuries; general principles in the handling of head, face and jaw wounds and wounds of the chest and genitourinary system; treatment of burns; problems and principles of transfusions under field conditions, including whole blood transfusions, direct and indirect transfusion technic and the use of blood substitutes to include plasma, albumin and electrolytes; administration of tetanus toxoid and gas gangrene serum; administration of vaccines; diagnosis and treatment of malaria; diagnosis and treatment of bacillary and amebic dysentery; diagnosis and treatment of dengue and typhus; prevention and treatment of heat stroke, heat exhaustion and heat cramps; prevention and treatment of freezing, frostbite, snow blindness and immersion foot, and the handling of neuropsychiatric cases.

The commanding officer of each general hospital will designate a training officer who will be responsible for the conduct, rotation and coordination of this training, ward rounds and clinics so that these officers can derive the maximum benefits from this limited period of "on the job" training.

AWARD OF SOLDIER'S MEDAL

A Medical Corps officer and four Medical Department enlisted men, all members of the Medical Detachment with a Coast Artillery battalion, have been awarded the Soldier's Medal for the rescue of injured persons from a burning ammunition barge in Sicily, the War Department announced recently. When responding to a call for emergency medical assistance, they rushed to the burning barge, where, in the midst of exploding ammunition and faced with the imminent danger of further major explosions, they succeeded in collecting the injured and transferring them to the shore for first aid and evacuation.

Through their efficient performance of duty and utter disregard of personal risk, many lives were saved. Those decorated were Capt. Samuel P. Durr, Medical Corps, Rock Island, Ill.; Corp. Rodney M. Preston, Jacksonville, Ill.; Private First Class John A. Dobrinski, New York, and Private Hubert Messenger, Kingman, Kan.

33D FIELD HOSPITAL

LIEUTENANT COLONEL SAMUEL A. HANSER, M.C., A.U.S.
Commanding 33d Field Hospital, APO No. 306

Because of the many inquiries with regard to the article about our hospital (THE JOURNAL, Nov. 20, 1943, p. 774) I am writing this explanation in regard to the use of field hospital platoons in the advanced combat zones. Since the Italian campaign began, this field hospital has had the opportunity of having its platoons behind the individual divisions as close to the front lines as possible.

The field hospital basically contains a headquarters and three platoons, and a total of twenty-two officers, eighteen nurses and one hundred and eighty-seven enlisted men. A platoon consists of four medical officers, one dental officer, one medical administrative officer and fifty-six enlisted men. When working in an

advanced combat zone it is reinforced by auxiliary surgical teams, usually four general surgical teams and one shock team. A surgical team consists of a surgeon, assistant surgeon, anesthesiologist, one nurse and two or three enlisted men.

The mission of a field hospital is to take care of nontransportable casualties, that is the patients whose conditions are critical and whose lives are endangered or lost by transporting them back to an evacuation hospital. The surgery is done by the best qualified surgeons in the theater.

During the Italian campaign we have taken care of 1,300 casualties and we feel that we have saved many lives by doing major surgical procedures in the advanced combat zone. The field hospital platoons have the finest of equipment, closed anesthesia machines, oxygen therapy machines, a blood bank and other vital necessities needed for the best possible surgery.

PRISONER OF WAR

Word has recently been received from Capt. Harry S. Hickman, formerly of Grants Pass, Ore., that he is being held a prisoner of war in the Philippines. Dr. Hickman graduated from the College of Medical Evangelists, Loma Linda, Calif., in 1940 and entered the service in October of that year.

NAVY

REGIMENTAL DOCTORS

Doctors assigned to a Marine regiment somewhere in the South Pacific pose in front of their sick bay. They are, left to right, Drs. Thomas E. Newell, Dayton, Ohio; Earl M.

the efficient treatment of battle casualties under extremely difficult and trying conditions. His brilliant leadership and untiring devotion to duty contributed in large measure to the successful care of many hundreds of patients." Dr. White graduated from Vanderbilt University School of Medicine, Nashville, in 1916 and has been in service since Aug. 20, 1917.

Medical officers assigned to a marine regiment in the South Pacific. Official U. S. Marine Corps Photo.

Haugrud, Fargo, N. D.; Max A. Finton, Jackson, Mich.; Maurice R. Walsh, Covington, Ky.; John V. Reilly, St. Louis, and Don P. Nebeker, Los Angeles. All are M.D.'s with the exception of Dr. Reilly, who is a D.D.S.

CAPT. JOEL J. WHITE AWARDED LEGION OF MERIT

Capt. Joel J. White, United States Navy, formerly of Nashville, Tenn., was awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as commanding officer of a naval hospital at an advanced base in the South Pacific Area from August 1942 to January 1943. Displaying outstanding professional skill and remarkable physical endurance, Captain White organized and operated a hospital in the New Hebrides Islands with a section assigned to Guadalcanal during the early period of operations at this strategic base. With utter disregard for his own personal safety he made repeated trips into the forward combat areas in order to develop facilities for

LIEUT. FRANK K. DEAN AWARDED BRONZE STAR

Lieut. Frank K. Dean, formerly of Madison, Wis., was awarded a bronze star for participating in the battle of Tarawa in November 1943, two months after reporting for duty as a member of the Navy Medical Corps. He previously had received an Asiatic Pacific campaign ribbon. Dr. Dean wrote to his wife, in Madison, that the ship on which he saw duty had carried no medical officer and he found no preparations or supplies when he went aboard. Just as the pioneer doctors, he was forced to improvise. From the ship's cook he commandeered tablespoons for retractors, forks for slings, and a pressure cooker for a sterilizer. Splints were whittled ashore, and a local station gave him sutures and plasma. Dr. Dean graduated from Northwestern University School of Medicine, Chicago, in 1935.

FIRST GRADUATING CLASS AT NEW HOSPITAL CORPS SCHOOL

Two hundred and twenty-four enlisted members of the Women's Reserve, U. S. Naval Reserve, graduated February 7 in the first graduating class of the newly commissioned Hospital Corps School at the U. S. Naval Hospital, Bethesda, Md. Twenty-two finished the intensive four week course with the rating of pharmacist's mate, third class; 146 as hospital apprentice, first class, and fifty-six as hospital apprentice, second class. Rear Admiral C. W. O. Bunker, medical officer in command of the National Naval Medical Center, and Capt. W. J. C. Agnew, Medical Corps, U. S. Navy, of the Bureau of Medicine and Surgery, addressed the graduating class, and certificates were presented by Capt. John Harper, commanding officer of the Hospital Corps School.

FIRST NAVY NURSES IN EUROPE

One hundred navy nurses, the first to set foot on European soil since the beginning of the war, have arrived in England for assignment to duty in a British hospital which is being taken over by the Navy. Lieut. Comdr. Mary Martha Heck, A. N. C., is in command and will direct all navy nursing activities in the European theater.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

LATIN AMERICAN MEDICAL GRADUATES SERVING AS INTERNS AND RESI- DENTS IN U. S. HOSPITALS NOT COUNTED IN QUOTA

At a recent meeting of the Directing Board, Procurement and Assignment Service, it was decided that graduates of Latin American medical schools currently serving as interns or residents would not be counted in hospital quotas.

It was felt that most Latin American doctors who accepted internships or residencies were in fact postgraduate fellows

attached to U. S. hospitals. In some instances language difficulties precluded their rendering as much medical care to hospital patients as native born and U. S. trained house officers. If Latin American physicians were to be counted in hospital quotas, there would be some hesitancy in accepting them in lieu of native born United States medical graduates.

Since it is highly desirable to have Latin American physicians seek postgraduate medical training in the United States, dropping them from hospital quotas would encourage hospital superintendents to accept them as interns and residents and thus facilitate their securing additional training in this country.

CIVILIAN DEFENSE

NEW OCD CHIEF MEDICAL OFFICER STATES FUTURE POLICY

The U. S. Office of Civilian Defense announces that Dr. W. Palmer Dearing, senior surgeon, U. S. Public Health Service, has been appointed chief medical officer, effective March 1, to succeed Dr. George Baehr, who has served as chief medical officer since June 1, 1941. Dr. Courtney M. Smith, senior surgeon (R), U. S. Public Health Service, formerly regional medical officer of the Ninth Civilian Defense Region (West Coast), will become assistant chief medical officer. Dr. Wallace M. Chapman, surgeon (R), U. S. Public Health Service, will succeed Dr. H. van Zile Hyde as field casualty officer, and Dr. Charles C. Chapple, surgeon (R), U. S. Public Health Service, will succeed Dr. Karl J. Thomson as intelligence officer. Dr. Dearing released the following statement:

"The Emergency Medical Service, the casualty receiving and emergency base hospitals, the plans for emergency medical service to industrial plants and the plans for mutual aid on a state-wide or regional basis for distribution in an emergency of personnel, equipment and supplies, including blood plasma, must be maintained.

"The affiliated units consisting of fifteen physicians, surgeons and specialists commissioned in the Public Health Service Reserve, which are available for call to render aid to civilians or to military personnel in a war emergency, will continue to maintain their organization for service when needed. They will be activated by the Surgeon General of the Public Health Service on recommendation of the state chief of Emergency Medical Service through the chief medical officer, Office of Civilian Defense. The circumstances under which they will be called to serve are set forth in OCD Circular, Medical Series No. 31. Likewise, affiliated nurses' units which have been recruited to serve in such emergencies are composed of twenty-two nurses each who have special civil service appointments. The file of names will be kept current in the Emergency Medical Section of the Public Health Service and in the regions where organized.

"The blood plasma banks which have been established in 180 hospitals with the assistance of grants-in-aid from the Public Health Service on recommendation of the Office of Civilian Defense will continue to maintain their reserves of plasma, which can be dispatched as needed by the local or state chiefs of Emergency Medical Service. In addition, the 29,500 units of frozen and 50,000 units of dried plasma procured by the Public Health Service and distributed to the physicians and hospitals of the Emergency Medical Service will continue to be available. Dr. John B. Alsever, surgeon (R), U. S. Public Health Service, will continue to exercise technical supervision of the plasma program and to consult with hospitals on their plasma problems.

"The Rescue Service, which was recently inaugurated following two nationally sponsored pilot schools at Pittsburgh and at Berkeley, Calif., is being developed under the direction of Mr. Philip Miller, engineer (R), U. S. Public Health Service, chief rescue officer. Rescue personnel trained in the pilot schools are conducting training schools in states and communities. This training has already paid dividends in lives saved at disasters such as the Easton, Pa., explosion and fire, the wreck of the

Congressional Limited, the disaster from the explosion at Kearney, N. J., and other lesser catastrophes.

"The gas protection program will be continued under Dr. Alberto F. Thompson Jr., sanitarian (R), U. S. Public Health Service, chief gas officer. Local gas reconnaissance specialists will be encouraged to maintain their organizations at peak efficiency by locally sponsored and conducted refresher courses for which the newest and most satisfactory methods of detection and recognition of gases will be available. Consultative assistance will be provided to states and communities by the Office of Civilian Defense when requested. More emphasis will be placed on the routine hazards surrounding manufacture, transportation and storage of toxic chemicals, hazards which can be dealt with only by chemically trained persons.

"The sanitary engineering program, including the mutual aid water program, will be continued under state and local auspices with the guidance of the U. S. Public Health Service. The Public Health Service was directed by the President to assume responsibility for security of public water supplies, and the engineering staff of the Medical Division has been transferred to the Public Health Service to operate the two programs concurrently and to serve in a consultant capacity to the O. C. D.

"The recent reduction of the staff of the National Office of Civilian Defense makes it imperative that states and communities assume more responsibility for these activities. The Emergency Medical Service organization in the field and in hospitals has repeatedly demonstrated its value in the disasters which wartime hazards have brought on us in increasing numbers. For the first time the health medical facilities of our communities have been organized for effective mobilization in the event of an emergency, and these gains should not be allowed to lapse. It is desirable that the Emergency Medical and Rescue Services be allied with permanent agencies of state and local government.

"In many localities the Emergency Medical Service has already been established under the health department. This has many advantages because the health department is a professional organization with the administrative machinery and personnel already at hand to maintain leadership, keep records and serve as the coordinating center in an emergency. Those cities having a department of hospitals may find it advantageous to establish and maintain the Emergency Medical Services under their jurisdiction. It would be desirable for this pattern to be extended to those communities which have established the Emergency Medical Service on a temporary basis without any relation to permanent agencies. Similarly, the Rescue Service might well be established in the public works department. Rescue work requires heavy equipment, tools, trucks and strong willing hands. The permanence of the public works department will be of great assistance in maintaining the organization.

"The emergencies which have been created by the war have borne fruit in the consolidation of community thinking and action in the protection of their communities. With the maintenance of a well trained and equipped Emergency Medical Service, every community will be prepared to give adequate care to injured and to save lives which otherwise would be lost. It appears certain that this cooperative and constructive spirit will be preserved in the organized Emergency Medical Services of the Citizens Defense Corps throughout the country."

ORGANIZATION SECTION

OFFICIAL NOTES

COUNCIL ON MEDICAL SERVICE AND PUBLIC RELATIONS

A meeting of the Council on Medical Service and Public Relations was held in Chicago on February 14 and 15. The following members were in attendance: Dr. Louis H. Bauer, chairman, Dr. James E. Paullin, Dr. James R. McVay, Dr. W. S. Leathers, Dr. E. J. McCormick, Dr. Alfred W. Adson, Dr. John H. Fitzgibbon and Dr. G. Lombard Kelly, secretary. The subjects discussed included:

FELLOWSHIPS IN A. M. A. FOR MEDICAL STUDENTS

The Council will recommend to the House of Delegates that the Board of Trustees work out a plan whereby medical students in approved schools can become student members of the American Medical Association and that the Board recommend the necessary changes in the Constitution and By-Laws to accomplish this. The idea of this recommendation is to inculcate medical students with the ideals of the medical profession and the medical societies.

COURSES IN MEDICAL ECONOMICS, SOCIOLOGY AND ETHICS

It was also decided to request the Council on Medical Education and Hospitals to consider taking the necessary steps as soon as possible to have each medical school give a course on medical sociology, medical economics and medical ethics.

PLATFORM OF THE A. M. A.

The Council decided to study the platform of the American Medical Association adopted in 1937 with a view to revising it bringing it up to date and then to refer the revised platform to the House of Delegates for consideration.

ANALYSIS OF MEDICAL PLANS

The Council considered various medical service plans, including the up-to-date analysis of society-sponsored plans by the Bureau of Economics. It discussed various industrial plans and has the whole subject of voluntary insurance under study. It also considered the question of diagnostic laboratories and medical service bureaus and likewise has them under further study.

VETERANS BUREAU

A considerable discussion was devoted to the status of medical service of the Veterans Bureau, and a conference will be asked

with officials of the Veterans Bureau to see in what way the Council can cooperate with them in improving the status of the medical service.

THE BUDGET

A budget was adopted and referred to the Board of Trustees.

COOPERATION WITH STATE SOCIETIES

All state societies are requested to send a copy of their state journals to the office of the Council in Chicago so that the Council can keep informed of actions taken in various states.

INDIANA PLAN TO COMBAT WAGNER-MURRAY-DINGELL BILL

The Council studied the speaker's kit compiled by the Indiana State Medical Association in its fight against the Wagner-Murray-Dingell Bill and considered it an excellent collection of material and invites attention of the other states to what Indiana has accomplished in this regard.

MEETING IN WASHINGTON

The Council decided to hold its next meeting in Washington, D. C., and to devote one day of its meeting to a conference with various agencies concerned in medical care.

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at 4:30 p. m. Eastern war time (3:30 Central war time, 2:30 Mountain war time and 1:30 Pacific war time).

The titles and guest speakers for the next three programs are as follows:

March 11. "Battles Won in Laboratories."

Speaker, A. C. Ivy, Ph.D., M.D., Northwestern University.

March 18. "You Must Help Win This War."

Speaker, H. A. Vonachen, M.D., medical director, Caterpillar Tractor Company, Peoria, Ill.

March 25. "Our Blood for Our Boys."

Speaker, G. Canby Robinson, M.D., national director, Blood Donor Service, American Red Cross, Washington, D. C.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—A subcommittee of the Senate Committee on Commerce has voted to submit an unfavorable report to the full committee with regard to S. 1096, creating a Bureau of Vital Statistics in the United States Public Health Service. A subcommittee of the House Committee on Interstate and Foreign Commerce has been conducting public hearing on H. R. 3379, to codify the laws which relate to the Public Health Service.

Bills Introduced.—H. R. 4251, introduced, by request, by Representative Bland, Virginia, proposes to give honorably discharged, disabled or retired marine employees of the Panama Canal a preference under civil service and to extend to them the facilities of the Public Health Service. H. R. 4255, introduced, by request, by Representative Barry, New York, proposes to amend the law relating to the Federal Trade Commission so as to authorize that commission to require in any order it may issue the publicizing by radio or printed advertising the

contents of the order by the person, partnership or corporation complained of, the publicizing being at the expense of the person, partnership or corporation. H. R. 4260, introduced, by request, by Representative Pace, Georgia, proposes to amend the Agricultural Adjustment Act to provide for the maintenance and operation of school lunch programs.

STATE MEDICAL LEGISLATION

Kentucky

Bill Introduced.—H. 366 proposes to authorize the state board of health to give medical scholarships of \$600 annually to bona fide residents of Kentucky who agree in writing to pursue medical courses in accredited medical colleges in Kentucky and after graduation and completion of internships of not exceeding two years to engage continuously in the practice of medicine in rural communities in Kentucky, to be selected by the state board of health, for a period of years equal to the number of years that each is a scholarship beneficiary.

Mississippi

Bills Introduced.—H. 401 and H. 455 propose to provide a system of workmen's compensation for industrial accidents. H. 531 proposes to make it unlawful for any person to employ another, or for any person to accept the employment, as a domestic servant unless within thirty days after the date on which the employment commences the domestic servant submits to a medical examination to be performed by a licensed physician. Such employment can then continue only if, on the basis of that examination, the examining physician issues a certificate that the domestic servant is apparently free from syphilis, gonorrhea, tuberculosis or typhoid fever. S. 267 proposes to appropriate \$54,000 to provide funds with which the state board of health and the state department of education may cooperate with the international health division of the Rockefeller Foundation and the general education board, respectively, in carrying out a program of coordinated school, health and nutrition services. S. 261 proposes to require annually as a prerequisite for the employment of all public school teachers and other state employees working directly with children an "x-ray analysis by a competent physician or by the state health department." The bill proposes that, if such examination "shows a positive result," the services of that employee shall be terminated for work with children so long as in the opinion of a competent physician or the state health department the tuberculosis is in an active and contagious stage. H. 503 and H. 527 propose to establish a four year medical school and hospital, to be known as the University of Mississippi Medical School and Hospital. H. 406 proposes to authorize the counties, cities or towns or supervisors' districts, separately or jointly, to establish and operate hospitals and to cooperate with the Works Progress Administration, or other agency of the United States government, or with one or more counties or one or more cities, or combination thereof, and the state, in the establishment and operation of those hospitals.

New York

Bills Introduced.—S. 898 and A. 1167, to amend the uniform narcotic drug act, propose, among other things, to prohibit supplying of narcotics for nonmedical needs or for the treatment of drug addiction when the patient is not confined to an institution, hospital or home, or for the satisfaction of a narcotic habit not complicated by an emergency or the presence of an incurable disease. S. 934, to amend the laws relating to the practice of medicine, proposes that licentiates be required to register on or before March 1 in each even year, rather than

of each year as now required. A. 1355 proposes that the state pay to any person injured by a dog the medical expenses, not to exceed \$100, incurred by reason of the injury. The owner of the dog or dogs involved is to be liable to the county in reimbursement for the amounts so paid. A. 1452 proposes to establish in the state health department an insurance fund to pay for necessary medical care for all persons insured by the fund. The scheme applies to all persons employed in the state at wages not in excess of \$2,500 and is financed by compulsory contributions from the employer and employee and from the state.

New Jersey

Bills Introduced.—A. 134, to amend the medical practice act, proposes to permit the board of medical examiners during the present war and for a period of three months after its cessation to admit an applicant to examination for a license to practice who has completed not less than nine months of an internship acceptable to the board in a hospital approved by the board. The bill also proposes to authorize the revocation of a license of a licentiate who has plead nolo contendere, non vult contendere or non vult to an indictment, information, complaint or accusation alleging the commission of the crime of criminal abortion or of crime involving moral turpitude. A. 135, to amend the medical practice act, proposes to exempt from the provisions thereof a chiroprapist "while operating in each particular case under the specific direction of a regularly licensed physician or surgeon."

Rhode Island

Bill Introduced.—H. 748 proposes to appropriate \$25,000 to be expended under the direction of the state director of health for the hospitalization of wives and children of men in the armed services below the grade of commissioned officers who are unable to pay for necessary hospital care.

South Carolina

Bill Introduced.—H. 1052 proposes to permit as a deduction in computing net income subject to taxation "all monies paid by individuals" to hospitals for hospitalization, and also all monies paid for medicines, services of nurses and services of physicians during hospitalization."

Virginia

Bill Introduced.—Substitute for S. 103 proposes to make incurable insanity a ground for divorce.

MISCELLANEOUS

OFFICE OF VOCATIONAL REHABILITATION OF FEDERAL SECURITY AGENCY

The first meeting of the Professional Advisory Committee of the Office of Vocational Rehabilitation of the Federal Security Agency was held in Washington on Friday March 3.

Present were the following members of the committee representing the professional specialties most actively concerned in rehabilitation:

- Rev. John W. Barrett, Chicago, director of Catholic hospitals, Archdiocese of Chicago
- Miss Harriet Bartlett, Boston, president, American Association of Medical Social Workers
- Dr. E. M. Bluestone, New York, director, Montefiore Hospital
- Dr. Karl M. Bowman, San Francisco, president-elect, American Psychiatric Association
- Dr. Roderick Brown, Pittsburgh, tuberculosis specialist
- Dr. Guy A. Caldwell, New Orleans, secretary, American Board of Orthopedic Surgery.
- Dr. John S. Coulter, Chicago, member, Council on Physical Therapy, American Medical Association
- Dr. Purman Dorman, Seattle, ophthalmologist
- Dr. Robert Elman, St. Louis, associate professor of clinical surgery, Washington University School of Medicine
- Miss Marjorie Fish, New York, in charge, Professional Courses in Occupational Therapy, Columbia University
- Lieut. Col. Raymond Hussey, M. C., A. U. S., Baltimore, director, Army Industrial Hygiene Laboratory
- Dr. Victor Johnson, Chicago, secretary, Council on Medical Education and Hospitals, American Medical Association
- Dr. E. S. Mariette, Minneapolis, medical director and superintendent, Glen Lake Sanatorium

- Dr. Horace Newhart, Minneapolis, professor emeritus of otology, rhinology and laryngology, University of Minnesota Medical School
- Dr. Winthrop M. Phelps, Baltimore, orthopedic surgeon
- Miss Marion Randall, Washington, D. C., chief nurse, Medical Division, Office of Civilian Defense
- Dr. W. D. Stroud, Philadelphia, member, Council on Industrial Health, American Medical Association
- Dr. V. P. W. Sydenstricker, Augusta, Ga., professor of medicine, University of Georgia School of Medicine
- Dr. H. A. Vonachen, Peoria, Ill., medical director, Caterpillar Tractor Company
- Mr. Frank J. Walter, Denver, president, American Hospital Association

Also attending the meeting by invitation were these members of the Rehabilitation Advisory Council:

- Dr. Kendall Emerson, New York, managing director, National Tuberculosis Association
- Dr. Carl M. Peterson, Chicago, secretary, Council on Industrial Health, American Medical Association
- Dr. Donald C. Snelzer, Philadelphia, president-elect, American Hospital Association
- Dr. George Stevenson, New York, medical director, National Committee for Mental Hygiene
- Miss Catherine Worthingham, Palo Alto, Calif., president, American Physiotherapy Association

The committee, made up of twenty specialists in medical and allied fields, was appointed by Administrator McNutt to provide professional guidance in mapping the new state-federal program for medical and surgical care under the Barden-LaFollette act.

Physical restoration for the handicapped, so that they may as nearly as possible approximate normal capacity, was called the

basic need in vocational rehabilitation by Federal Security Administrator Paul V. McNutt. In opening the meeting he stressed the Federal Security Agency's desire to aid the states in providing physical restoration services which will conform to the high professional standards recognized by the national and state medical associations and by the hospital associations.

"To be able to count on themselves as workers," Mr. McNutt continued, "many of the disabled need more than vocational training, important as that is. They need medical care to restore as much physical capacity as possible. Doctors have long pointed out that tackling the complex problem of rehabilitation at any other point is putting the cart before the horse. Some of the states too have pioneered in providing for physical restoration, along with vocational training, for the handicapped. This service has now been recognized as an integral part of our national vocational rehabilitation program.

"We want to give the disabled—the men and women crippled in industry or by accident or illness—a chance to fulfil their rights and duties as citizens and as self-supporting wage earners. We want to do this because it is in line with the American way of looking out for ourselves. We want to do it now, because war industry needs every hand that can help."

An estimated million and a half persons may be eligible for rehabilitation under the program authorized by the enactment of the Barden-LaFollette bill last summer, according to a statement by Michael J. Shortley, director, Office of Vocational Rehabilitation.

Reporting the total active case load as 91,000 for the current year, he said that "the states indicate they will extend rehabili-

tation services to 110,000 disabled persons during the fiscal year 1945." The program is in operation in all forty-eight states, the District of Columbia, Hawaii and Puerto Rico. "Physical restoration rounds out vocational rehabilitation services. It gives us the chance," he said, "to do more things for more people."

The committee reviewed the basic plans, policies and regulations governing the program in a discussion led by Mr. Shortley. Plans for organization were brought before the committee by Dr. Dean A. Clark of the U. S. Public Health Service, who is chief medical officer for the Office of Vocational Rehabilitation. Particular consideration was given to the method of insuring that patients receive medical service of the highest quality. The committee stressed the importance of strong and well selected medical advisers for the state rehabilitation agencies to assure that satisfactory standards for the selection of specialists and facilities are established and followed in the state programs. In order to maintain high standards, the desirability of providing fair and adequate remuneration for the necessary services was emphasized.

The particular problems associated with the rehabilitation of persons having psychiatric disabilities, tuberculosis or orthopedic, cardiac, visual and auditory handicaps were discussed at length by the specialists of the committee. The committee also made recommendations on the scope of physical restoration services, auxiliary services in the fields of medical-social work, nursing, psychiatric social work, physical and occupational therapy, and definition of the policies and plans for various groups of disabilities.

AMERICAN BAR ASSOCIATION COMMITTEE REPORTS ON PARTS OF WAGNER-MURRAY BILL (S. 1161) RELATING TO FEDERAL REGULATION OF MEDICINE

At the meeting of the American Bar Association held in Chicago, Aug. 23-26, 1943, the House of Delegates on August 26 adopted the following resolution:

Resolved, That the Board of Governors be requested to appoint immediately a special committee to study, analyze and investigate Senate bill 1161, and that the Board of Governors give publicity to the recommendations and findings of such special committee and the action of the Board of Governors thereon; be it further

Resolved, That the House of Delegates is opposed to any legislation, decree or mandate that subjects the practice of medicine to federal control and regulation beyond that presently imposed under the American system of free enterprise.¹

In accordance with the foregoing resolution of the House of Delegates the undersigned committee was appointed by the Board of Governors.

ANALYSIS OF SENATE BILL 1161

The committee has given considerable study to title IX of the Social Security Act as amended by S. 1161 (title IX being herein sometimes referred to as section 11 of S. 1161 or as the Socialized Medicine bill). The entire bill covers 90 pages. It amends the Social Security Act approved Aug. 14, 1935² by adding under new titles the following subjects:

- I-A—Unified National Social Insurance System (p. 2);³
- I-B—A National System of Public Employment Offices (p. 3);
- II-A—Social Security Protection to Individuals Engaged in the Military Service (p. 26);
- VIII-A—Unemployment Compensation Allowances on Termination of Military Service (p. 36);
- IX—Federal Medical, Hospitalization and Related Benefits (p. 39);
- IX-A—Federal Social Insurance Contributions (p. 58);
- XII—Unified Public Assistance Program (p. 82).

While your committee is concerned only with title IX, having to do with federal medical, hospitalization and related benefits, it has been found necessary to give some study to title IX-A—Federal Social Insurance Contributions in order to estimate the amount of tax money and the number of individuals involved in the proposed socialized medical system.

It is impossible for the general public to secure an accurate idea of the Socialized Medicine bill. Being a part of an extensive piece of proposed legislation, on other parts of which it is dependent, and prepared in a form which has become popular in the past ten years, being replete with involvement, cross references, new terminology, percentages and other confusing matters, the socialized medicine chapter leaves the reader in utter confusion as to its meaning or extent. As an example of the verbiage that causes such confusion we cite the following: The bill appears to entitle every individual who is currently insured and has been found by the board to be eligible for benefits under title IX in a current benefit year to receive general medical, special medical, laboratory and hospitalization benefits after the effective date of the title.

Who is "currently insured"?

" . . . An individual shall be deemed to be 'currently insured' if it appears to the satisfaction of the board that (1) he had acquired not less than two quarters of coverage during the four calendar quarters immediately preceding the quarter in which he died or in which his disability began (excluding from such immediately preceding quarters any quarter for any part of which he was under a prior disability), or (2) during his eligibility period (as defined in title XI) he had been paid wages of (a) not less than \$150, and (b) not less than \$50 for each of not less than two calendar quarters." [Sec. 209(h) p. 24]

What is his "eligibility period"?

" . . . 'Eligibility period' means the first four of the last six completed calendar quarters immediately preceding the first day of a benefit year." [Sec. 1101 (a)(7), p. 73]

At great pains and with the expenditure of considerable time your committee has undertaken to analyze the Socialized Medicine title and break it down into simple language. To this end it has set out (1) the authority of the Surgeon General, (2) the authority and powers of the Social Security Board and (3) the cost of the scheme.

1. American Bar Association Journal, October 1943, p. 602.
2. 49 Stat. at L. p. 620, 42 U. S. C. A., sections 301 et seq.
3. Page references are to the printed bill, S. 1161.

The bill provides that every individual currently insured⁴ shall be entitled to receive general medical, special medical, laboratory and hospitalization benefits. Every dependent wife and child of and living with an individual who is currently insured is likewise entitled thereto [S. 1161, sec. 901(b) p. 39]. This includes thirty days' hospitalization each year, subject to an increase to ninety days per annum if the Surgeon General of the Public Health Service and the Social Security Board find that the Medical Care and Hospitalization Account are adequate [ibid. sec. 902 p. 40].

Authority of the Surgeon General.—The Surgeon General is authorized or required

(a) To take all necessary and practical steps to arrange for the availability of the benefits and of services to those entitled to the same⁵ [S. 1161, sec. 903(a) p. 40].

(b) To make and publish, with the approval of the Federal Security Administrator, such rules and regulations as may be necessary to enforce title IX [ibid. sec. 914 p. 55].

(c) To prescribe rules under which any physician legally qualified by a state to practice shall be qualified to furnish services [ibid. sec. 905(1) p. 44].

(d) To publish and make known in each area the names of general practitioners who have agreed to furnish their services [ibid. sec. 905(3) p. 44].

(e) To prescribe the maximum number of potential beneficiaries for whom a practitioner may undertake to furnish general medical benefit, which may be uniform nationally, or may be adapted to take account of relevant factors, as the Surgeon General may determine [ibid. sec. 905(10), p. 47].

(f) To prescribe rules and regulations under which every individual who is entitled to receive as a benefit services from a physician and who is permitted to choose from among those designated by the Surgeon General (except specialist services) may change his selection [ibid. sec. 905(2), p. 44].

(g) In any area where payment is on a per capita basis, to distribute on a pro rata basis among the practitioners selected in the area those individuals who have failed to make a selection, or who having made one have been refused by the practitioner [ibid. sec. 905(11), p. 47].

(h) To determine (with the Social Security Board) for any calendar year or part thereof that every individual entitled to benefits may be required by the physician furnishing the same to pay a fee with respect to the first service or with respect to each service in a spell of sickness or course of treatment, if such payment may be desirable to prevent or reduce abuses of entitlement to such benefit; to limit the application of such fees to home calls, to office visits or to both, to fix the maximum total amount of such fee payments in a spell of sickness or course of treatment, and to provide for differences in the size or total amount of fee payments for urban and rural areas and with regard for differences among states or communities [ibid. sec. 911(a), p. 51].

(i) To select and designate the specialists to serve and to determine the class of services each specialist shall furnish [ibid. sec. 905(4), p. 45].

(j) To approve payments from the Federal Social Insurance Trust Fund⁶ to practitioners and specialists which shall be made according (A) to a schedule of fees, (B) on a per capita basis, (C) on a salary basis for part or whole time or (D) a combination or modification of all of these, according in each area as the majority of general medical practitioners so paid shall elect, subject to necessary rules and regulations of the Surgeon General. Payments may be nationally uniform or "may be adapted to take account of relevant factors" [ibid. sec. 905(7)(8)(9), pp. 46, 47].

4 Any individual is deemed to be currently insured if it appears that (1) he had acquired not less than two quarters of coverage during the four calendar quarters immediately preceding the quarter in which he died or in which his disability began, or (2) during his eligibility period he had been paid wages of (a) not less than \$150 and (b) not less than \$50 for each of not less than two calendar quarters [ibid. sec. 209(b) p. 24]. "Eligibility period" means the first four of the last six completed calendar quarters immediately preceding the first day of a benefit year [ibid. sec. 1101(a)(7) p. 73].

5 There are two classes of benefits: (a) "general medical benefit" including all services generally performed by a practicing physician and (b) "special medical benefit" being services performed by a specialist with respect to any particular class of service [ibid. sec. 915(a)(b) p. 55]. No individual is entitled to any benefit if the illness or disability is covered by any workman's compensation law [ibid. sec. 909, p. 50].

6 The Federal Social Insurance Trust Fund consists of the securities held by the Secretary of the Treasury for the Federal Old Age and Survivors Insurance Trust Fund and the amounts standing to the credit of the Federal Old Age and Survivors Insurance Trust Fund on the books of the Treasury on Jan. 1, 1944, any other amounts as may be paid into or belong to the Trust Fund, and the contributions collected under title IX [ibid. sec. 969(a), p. 67].

(k) To publish a list of participating hospitals⁷ and revise the same from time to time by withdrawing therefrom existing hospitals or adding others [ibid. sec. 907(a), p. 49].

(l) To determine, with the approval of the Social Security Board, the amount to be paid for hospitalization benefit, which shall be not less than \$3 and not more than \$6 for each day of hospitalization, not in excess of thirty days, which an individual has had in a period of hospitalization; and not less than \$1.50 and not more than \$4 for each day of hospitalization in excess of thirty in a period of hospitalization; and not less than \$1.50 and not more than \$3 for each day of care in an institution for the care of the chronic sick. In lieu of such compensation, after approval by the Social Security Board, to enter into contracts with participating hospitals for the payment of the reasonable cost of hospital service, at rates for each day of hospitalization neither less than the minimum nor more than the maximum applicable rates specified in this subparagraph (l), such payment to be full reimbursement for the cost of essential hospital services, including the use of ward or other less expensive facilities [ibid. sec. 915(g), p. 57].

(m) To select hospitals for selected varieties of cases and institutions for the care of the chronic sick, and in doing so to take into account the purpose of such limited accrediting, the type and size of community which the institution serves, the availability of other hospital facilities, and such other matters as he may deem relevant [ibid. sec. 915(f), p. 56].

(n) To make findings of fact and decisions as to the status of any institution as a participating hospital⁸ in accordance with general standards previously prescribed by him after consultation with the council⁹ [ibid. sec. 907(b), p. 49].

(o) To negotiate agreements for supplies and commodities necessary for the benefits provided [ibid. sec. 903(b), p. 40].

(p) To limit (with the Social Security Board) for any calendar year or part thereof the cost of laboratory benefit which shall be borne by payments from the Trust Fund, and such limitation may be with respect to a class of services, supplies or commodities, with respect to maximum payments per beneficiary in a benefit year, with respect to a specified fraction of the cost or combinations thereof [ibid. sec. 911(b), p. 52].

(q) To determine what shall be included in laboratory benefits, including chemical, bacteriologic, pathologic, diagnostic and therapeutic x-ray, physical therapy, special appliances prescribed by a physician, and eye glasses [ibid. sec. 915(c), p. 55].

(r) To make provisions by which persons not entitled to benefits may use the services and institutions provided for the currently insured, for which the Trust Fund shall be reimbursed [ibid. sec. 903(b), p. 40].

(s) To negotiate agreements, approved by the Social Security Board, under which benefits may be furnished to individuals not entitled to the same for any period for which payments have been made, or assurances of such payments have been given by public agencies of the United States, of the several states or of their political subdivisions. The benefits shall be the same, so far as practical in each area, as those furnished to individuals entitled to such benefits [ibid. sec. 910(a), p. 50].

(t) Through agreement or cooperative working arrangement, use the services and facilities of other federal, state or municipal agencies [ibid. sec. 1108(b), p. 75].

(u) To negotiate agreements with public and private agencies or institutions or with private persons or groups, to utilize their services and facilities and to pay for the same [ibid. sec. 903(b), p. 40].

7. A participating hospital is an institution providing all necessary and customary hospital services, which is found by the Surgeon General to afford professional service, personnel and equipment adequate to promote the health and safety of individuals customarily hospitalized in such institution and to have procedures for the making of such reports and certifications as the Surgeon General and the Social Security Board may from time to time require, to assure that hospitalization benefit will be provided only to or on behalf of individuals entitled thereto [ibid. sec. 915(f), p. 56].

8. Any institution may file a petition with the Surgeon General to be included in the list of participating hospitals, the petition to set forth such information as the Surgeon General may deem necessary to establish that such institution meets the requirements of a participating hospital. Any institution whose petition the Surgeon General has denied may request a hearing with respect to the decision, and the Surgeon General shall grant such hearing and shall affirm, modify or reverse his prior decision [ibid. sec. 907(b), p. 49].

9. The National Advisory Medical and Hospital Council is organized by the Surgeon General. The Council is authorized to advise the Surgeon General with respect to professional standards, designation of specialists, methods to stimulate high standards through coordination of services of practitioners, specialists, laboratories and so on and of services of practitioners with those of educational and research institutions, hospitals and health centers; with respect to standards to apply to participating hospitals and the establishment and maintenance of a list of participating hospitals, adequate and suitable methods of paying for services, surveys and surveys of the services furnished by practitioners, and of the quality and adequacy of such services, grants of aid for research, education and research projects, and establishment of special advisory technical, local or regional boards, committees or committees [ibid. sec. 904 (c), pp. 41-5].

(v) To administer grants-in-aid to nonprofit institutions and agencies engaged in research or in undergraduate or postgraduate professional education, such grants-in-aid to be made with respect to each project (1) for which application has been received from a nonprofit institution stating the nature of the project and giving the reasons for the need of financial assistance in carrying it out, and (2) for which the Surgeon General finds that the project shows promise of making valuable contributions to the education or training of persons useful to or needed in the furnishing of medical, hospital, disability, rehabilitation and related benefits provided under the act, or to human knowledge with respect to the cause, prevention, mitigation or methods of diagnosis and treatment of disease and disability¹⁰ [ibid. sec. 1111, p. 77].

(w) To report to and recommend legislation to Congress not later than two years after the law becomes effective with respect to the most effective methods of providing dental, nursing and other needed benefits not already provided for under the title, and as to expected costs for the same, and the desirable division of the costs between (1) the financial resources of the social insurance system and (2) payments to be required of beneficiaries receiving such benefits [ibid. sec. 912, p. 53].

(r) To appoint a board known as the National Advisory Medical and Hospital Council, of which the Surgeon General is chairman, consisting of sixteen members, each member to hold office for four years and receive \$25 per diem for services in attending meetings and in the performance of other duties [ibid. sec. 904(a), p. 41].

(y) To establish necessary and sufficient hearing and appeal bodies to hear and determine complaints from individuals entitled to benefits, from practitioners who have entered into agreements and from participating hospitals, and to hear and determine disputes among practitioners and participating hospitals, and to take steps to remedy the grounds of complaint, if any [ibid. sec. 906, p. 48].

(z) To have all the powers conferred on the Social Security Board, by sections 205 and 206 of the Social Security Act as amended; and the provisions of subsections (e) and (f) of section 205 and section 208 shall be applicable in the same manner and to the same extent as they are applicable to title II of the Social Security Act¹¹ [ibid. sec. 1108(a), p. 74].

Authority and Powers of the Social Security Board.—(a) All agreements shall be negotiated by the Surgeon General and approved by the Social Security Board, except as to fixing rates for hospitalization [S. 1161, sec. 903(b), p. 40].

(b) The board is authorized to enter into compacts with the states, or with the political subdivisions thereof, for the purpose of extending medical and other benefits to the employees of such states or political subdivisions. Each such compact shall provide

(1) That the benefits shall be the same as for other employees covered by insurance programs;

(2) That the state or political subdivision shall pay the employers' and collect the employees' contribution;

10. For these purposes there shall be available for each calendar year 1 per cent of the total amount expended for benefits from the Trust Fund, exclusive of unemployment insurance benefits, or 2 per cent of the amount expended for benefits under title IX, after benefits have been payable for not less than twelve months, whichever is the lesser. The amount under the 2 per cent provision is estimated to be \$46,780,000 for 1942.

11. Section 205 (a) [42 U. S. C. A., section 405 (a)] authorizes the board to make rules and regulations and to establish procedures necessary or appropriate to carry out the provisions of the act, and to adopt reasonable and proper rules and regulations to regulate and provide for the nature and extent of the proofs and evidence and the method of taking and furnishing the same in order to establish the right to benefits hereunder. Section 205 (c) [42 U. S. C. A., section 405 (c)] provides that in case of contumacy by, or failure to obey a subpoena served on any person, the Surgeon General may by application to the district court have such person cited and ordered to comply with such subpoena, subject to punishment for contempt for his failure to comply with the order of the court. Under section 205 (f) [42 U. S. C. A., section 405 (f)] no person shall be excused from giving testimony on the ground that the same will incriminate him, but such person should not be prosecuted on account of any matter about which he is required to testify.

By Section 206 [42 U. S. C. A., section 406] the Surgeon General may prescribe rules and regulations governing the recognition of agents or other persons representing claimants before the Surgeon General and may, after due notice and opportunity for hearing, suspend or prohibit from further practice before it any such person, agent or attorney who refuses to comply with the rules and regulations prescribed by the Surgeon General. He may also prescribe the maximum fees which may be charged for services performed in connection with any claim before the Surgeon General, and a violation of such regulation shall be subject to a fine not exceeding \$500 or by imprisonment not exceeding one year, or both.

By section 208 [42 U. S. C. A., section 408] any person making any false statement or representation or affidavit in connection with any application for any payments shall be punished by fine of not more than \$1,000 or imprisonment for not more than one year.

(3) That the compact must be in effect at least five years before the state can give a two year notice to the Social Security Board of its purpose to terminate the compact;

(4) That all employees shall be covered by old-age, survivors, permanent disability, medical and hospitalization insurance, except that no employee shall be so covered while he is a beneficiary or contributory member to or possessor of an unrealized interest in any pension, annuity and benefit or retirement fund or any similar fund which is in existence at the date such compact is entered into or maintained by authority of any existing federal or state law [ibid. sec. 966(a)(b), p. 65].

(c) The board shall establish a Federal Social Security Advisory Council composed of men and women representing employers and employees in equal numbers and the public for the purpose of formulating policies and discussing problems relating to social security legislation and administration, and to insure impartiality, neutrality and freedom from political influence in the solution of such problems¹² [ibid. sec. 1112(a), p. 78].

The board may also establish such councils for any part of the Social Insurance System or for any geographic area of the United States [ibid. sec. 1112(b), p. 79].

Cost of Benefits.—The Medical Care and Hospitalization Account is established as a separate account within the Trust Fund, to which the managing trustee¹³ shall credit amounts equivalent to—

(1) One fourth of the social insurance contributions paid in by employers and employees, amounting to 6 per cent of wages¹⁴ payable by each class, or a total of 12 per cent.

(2) Three sevenths of (a) the contributions paid in by self-employed individuals, which is at the rate of 7 per cent of their remuneration not in excess of \$3,000 per annum; (b) social insurance contributions payable by states and political subdivisions thereof, and by employees thereof equal on the part of each class to 3.5 per cent of wages, falling within the scope of a voluntary compact under section 966 [p. 65].

This account shall include also applicable shares of interest, penalties and additions to the contributions and a proportionate part of the earnings of the Trust Fund, determined in accordance with the average daily balance to the credit of this account [S. 1161, sec. 913(a)(b), p. 53].

The amount in this account shall be available only for the payment of or provision for benefits and for administrative expenses under title IX [ibid. sec. 913(e), p. 54].

A sum is appropriated sufficient for all necessary expenses in carrying out the duties imposed on the Social Security Board and the Surgeon General by the act, including the making of such studies and demonstrations and such provisions for the training of personnel as may be expected to improve the quality of the services and promote the efficient administration of title IX; and for the pay, allowances and travel expenses of commissioned officers (regular and reserve), noncommissioned officers, and other personnel assigned to duty in carrying out the purposes of title IX and in connection with the administration of grants-in-aid [ibid. sec. 1109, p. 75].

12. The Advisory Council shall, from time to time, make findings and recommendations to the board, particularly concerning (1) the administration of the Social Insurance System with respect to self-employed, agricultural labor, domestic service, employees of nonprofit institutions and employees of federal, state and local governments; (2) the administration of federal medical, hospitalization and related benefits in areas in which facilities and personnel are not adequate; (3) the adequacy of the benefits provided under the Social Insurance System in relation to the wage levels, cost of living and employment patterns, particularly in the postwar period, taking into account the cost and any other relevant factors of any suggested alternatives; (4) the methods of financing and the amount and distribution of the contributions to the Social Insurance System in the postwar period [ibid. sec. 1112 (c), p. 79].

13. The Secretary of the Treasury [ibid. sec. 969 (b), p. 68].

14. "Wages" means all remuneration for employment except (a) that part in excess of \$3,000 per annum, (b) the amount of any payment under a plan or system established by an employer which provides for payment on account of (1) retirement, (2) sickness or accident disability, medical and hospitalization expenses in connection with the same, (3) death (except under conditions providing other or substitute benefits), (c) dismissal payments not required to be made or (d) value of services exchanged for other services and other unimportant exceptions [ibid. sec. 962 (a), p. 59].

THE COST TO THE PUBLIC AND THE NUMBER OF
PERSONS COVERED

From the face of the bill no one can estimate how much tax money is involved or how many people are covered; so your committee has sought information on which to base answers to these questions. Table 1, based on data provided by the Social Security Board and the Treasury Department, is self explanatory.

TABLE 1.—Estimated Employment in United States,^a
Years 1940-1942^b

	1940		1941		1942	
	Number Employed (Millions)	Wages (Billions)	Number Employed (Millions)	Wages (Billions)	Number Employed (Millions)	Wages (Billions)
Total employment covered by old age and survivor insurance.....	40.5	\$36.1	40.9	\$45.4	44.9	\$56.6
Total employed by state and local governments.....	a	a	3.3	3.7	3.3	3.7
Total employed under Railroad Retirement Act....	1.2	2.1	1.3	2.5	1.4	3.1
Total "civilian employment" ^a	46.0	\$44.0	48.8	\$54.1	51.9	\$67.6
Self employed:						
Farm owners and tenants.....			5.1		5.1	
Other.....			5.7		5.7	
Total self employed ^c			10.8	10.1	10.8	12.1
Total employment ^a			59.6	\$64.2	62.7	\$80.7

a. Does not include those listed in table 2.

b. Source: Social Security Year Book 1942, p. 26.

c. There may be an undetermined amount of duplication in total "civilian employment." It would not change the total to any appreciable extent, however.

d. We do not have the number of the total employed by the federal government and their wages for 1940. The total employed by federal, state and local governments for this year is 4.3 (millions) and the wages 6.8 (billions).

From table 1, if the Socialized Medicine bill had been in effect in 1942,¹⁵ the following would have resulted:

Social Insurance Contributions.—(a) By employers and employees,¹⁶ 7.168 billion dollars; (b) by self employed,¹⁷ 0.917 billion dollars; total, 8.085 billion dollars; (c) by state and local governments and employees,¹⁸ 0.259 billion dollars; total, 8.345 billion dollars.

Of the foregoing taxes there is required to be credited to the Medical Care and Hospitalization Account $\frac{1}{4}$ of (a), 1.792 billion dollars; $\frac{3}{4}$ of (b) and (c), 0.547 billion dollars; total, 2.339 billion dollars.

We come now to the number of people covered by the scheme: Total employed in industry, 44.9 million; total employed by state and local governments, 3.3 million; total employed under Railroad Retirement Act, 1.4 million; total self employed, 10.8 million; total covered, 60.4 million.

It should be kept in mind that the 3,000,000 federal employees are not included in the scheme by reason of section 962(b)(2) [p. 61], which in defining "employment" excludes services performed in the employ of the United States. The reason for this is that federal employees (in Washington) have their own medical system, which is maintained by a 5 per cent salary reduction.

15. There are so many variables to be considered, it is difficult to compare the number of those employed and the wages paid in 1943 with those in 1942. Nor are we able to secure the figures for 1943 from any governmental bureau. Among such variables are the following: Many women are being employed in war industries and in manufacturing plants to replace men who have entered the services. The wage rates of the women are considerably lower than those of the men whom they replace. This has a tendency to lower the average wage rate for 1943 as compared with 1942. In October 1943 the number of agricultural workers showed a decrease under October 1942 of about 1 million, owing largely to the absorption of workers in the Army. In manufacturing industries the average annual wage per worker in 1942 was \$1,906; in 1943 it was \$2,223, or an increase of 17.2 per cent. This is due, however, in large measure to overtime work by employees.

16. 12 per cent of wages [S. 1161, sec. 960, p. 581.

17. 7 per cent of income [ibid. sec. 963, p. 63].

18. 7 per cent of income; based on voluntary compacts with state governments [ibid. sec. 964, p. 64].

In 1940 there were 34,855,000 occupied dwelling units, or approximately that many families. In the same year there were 52,789,000 persons in the "labor force."¹⁹ This means that there were about 1.51 members of the labor force for each household. Thus it is almost certain that practically every family had at least one member included in the labor force, either at work or seeking work.

Accordingly, if every individual worker is covered by this act (as it appears he may be if his earnings are at a prescribed minimum) coverage must include practically all families in the United States. So with virtually complete family coverage by the act there would be few or no patients left for physicians who prefer private practice to becoming a part of the Socialized Medicine scheme.

SENATOR WAGNER'S INTERPRETATION OF THE BILL

When Senator Wagner (and Senator Murray) introduced S. 1161 on June 3, 1943 Senator Wagner made the following statement with reference to title IX:

"Freedom of Medical Practice: There is no plan here, such as that lately considered in Britain, for a system of socialized medicine, with all doctors required to be salaried employees of the government. Unlike this British proposal, my bill assures complete freedom of choice of doctor and hospital by the patient, and freedom of medical practice and types of remuneration for the doctor and the hospital. No doctor is forced into the insurance system or forced on a salary status. Arrangements for obtaining medical, laboratory or hospital care would be essentially as they are now in this country, except that payment for the care and services would be out of the insurance fund, built up through the insurance premiums paid by the individual and his employer. Voluntary hospitals would, of course, be eligible to participate in the plan if they choose to do so and thus be enabled to expand their splendid community services. Nonprofit group medical or hospitalization plans may also be utilized in carrying out the program, and they would be in a position to offer supplementary health protection for families desiring more than the basic social insurance benefits guaranteed under the bill. In all its provisions this bill would promote the personal relations between doctor and patient and be adapted to the needs and practices of the individual community, and the wishes of the doctors in that community, in both rural and urban areas. Similar basic principles as to medical and hospital benefits and freedom of medical practices are embodied in a program recently put forward by the government of Canada, with the full accord of the Canadian Medical Association and the Canadian Hospital Council."²⁰

TABLE 2.—Occupations of Workers

	Thousands
1. Agricultural workers, including sharecroppers.....	4,000-5,000
2. Unpaid family workers in agriculture.....	2,000-3,350
4. Domestic workers in private homes and fraternities.....	2,000-2,300
6. Casual employees	750-1,000
8. Workers in nonprofit organizations.....	700-1,000
9. Students employed by schools and colleges in which enrolled	25-40
10. Employees of foreign governments and their instrumentalities	15-25
11. Student nurses and interns.....	5-10
12. Persons engaged on work relief programs.....	1,750-2,000
13. Fishermen employed on vessels of 10 tons or less (except halibut and salmon fishermen).....	15-20
14. Newsboys under age 18.....	275-325
15. Other employees in miscellaneous occupations.....	100-300
Total.....	12,925-15,270

Senator Wagner's Statement Not Accurate.—Of course Senator Wagner does not have the time to engage in the exhaustive studies necessary to enable him to discuss fully the effect of socialized medicine in this country and throughout the world. He must of necessity depend on his staff to provide these studies for him. He doubtless depends also on others who are active in promoting the measure.²¹ Those who have assisted the

19. U. S. Bureau of the Census.

20. Congressional Record 89:5344.

21. Inquiry from reliable sources in Washington indicates the probability that the actual designers and authors of S. 1161 are Isidore S. Falk and Wilbur J. Cohen, director and assistant director, respectively, of the Bureau of Research and Statistics of the Social Security Board, and Philip Levy, secretary to Senator Wagner.

Senator are not entirely accurate in some of their statements, and their conclusions and in some instances are entirely incorrect.

We point out the following inaccuracies in Senator Wagner's statement of June 3, 1943:

1. Senator Wagner states: S. 1161 is unlike the British proposal, which is the Beveridge plan with all doctors required to be salaried officers of the government.

The statement is misleading. Both plans look toward a system of medicine supervised, regulated and controlled by government. Under S. 1161 all doctors will be paid by the government, for in time there will be no private practice.

2. Senator Wagner states: There is complete freedom of choice of doctor by patient.

This is incorrect. If either the patient or the doctor named on the panel by the Surgeon General declines to accept the other, the patient is assigned to some other doctor.

3. Senator Wagner states: There is complete freedom of choice of hospital by patient.

This statement is incorrect. There is no provision for freedom of choice of hospital. The entire system is under regulation by the Surgeon General.

4. Senator Wagner states: There is freedom of medical practice for the doctor.

This is misleading. The plan is so extensive that in time there will be no private practice.

5. Senator Wagner states: There is freedom of types of remuneration for the doctor.

This is misleading. The doctor is forced on a salary or on a fee basis or on a combination of the two, as determined by the Surgeon General, who approves the fee tables.

6. Senator Wagner states: There is freedom of types of remuneration for the hospital.

This is incorrect. Hospital rates are determined by the Surgeon General with the approval of the Social Security Board.

7. Senator Wagner states: No doctor is forced into the insurance system.

This is misleading. He must go into the insurance system or be forced economically to cease the practice of medicine.

8. Senator Wagner states: No doctor is forced on a salary basis.

This is misleading. The doctor is forced on a salary or a fee basis, or on a combination of the two, as determined by the Surgeon General.

9. Senator Wagner states: Arrangements for obtaining medical, laboratory or hospital care would be essentially as they are now in this country, except as to payment out of the insurance fund.

This is entirely incorrect. The whole medical system is supervised, regulated and controlled by government.

10. Senator Wagner states: Voluntary hospitals are eligible to participate in the plan.

This is misleading. They may participate if selected by the Surgeon General.

11. Senator Wagner states: The system would promote the personal relations between doctor and patient.

This is an expression of opinion. The experience of foreign countries shows an opposite result.

12. Senator Wagner states: The Canadian system recently proposed is similar to S. 1161 and has the support of the Canadian Medical Association and the Canadian Hospital Council.

This is incorrect and misleading. The Canadian plan provides for its adoption by the provinces (or states) with a local full time doctor in charge. Both the Canadian Association and the Canadian Council are sharply critical of the plan.

Let us analyze Senator Wagner's statement further:

(1) The British Medical Association, which is comparable to the House of Delegates of the American Medical Association, at its meeting on Sept. 21-23, 1943 considered the Beveridge plan, although there was no definite legislative proposal available for consideration. No doubt Senator Wagner had this plan in mind in making his statement of June 3, 1943. The Beveridge plan contemplates a complete system of state medicine, with salaried physicians, involving the entire abolition of private medical practice. The report of the plan provides that the administration shall be confided to local governments with the minister of health in general supervision.

The action of the association was limited to statements of principles and general positions. By a vote of 200 to 10 the resolution was adopted opposing the creation of a whole time

salaried state medical service as not being in the best interest of the community.

The Representative Committee, which had been appointed to study the report, submitted an extensive report stressing, among other things, the necessity of free choice as between doctor and patient; that the loyalty and obligation of a doctor should be to the individual patient and to none other; that it was not in the public interest that the state should convert the medical profession into a salaried branch of central or local government service; and that the state should not assume control of doctors rendering individual or personal health service.²²

It would therefore appear that the Beveridge plan retains elements of local control which do not exist in Senator Wagner's bill.

(2, 3) There is no "freedom of choice" of doctor by patient, as we know that term today. The statute permits every individual to select those from whom he shall receive services, but his selection must be confined to one or more physicians furnishing such services under the direction of the Surgeon General [S. 1161, sec. 905(1)(2), p. 44]. The patient may change his selection, but only according to rules and regulations prescribed by the Surgeon General [ibid. sec. 905(2), p. 44].

If a practitioner selected by any individual refuses to serve the latter, the individual may, with others, be "distributed" by the Surgeon General on a pro rata basis among the other practitioners [ibid. sec. 905(11), p. 47]. There is no provision for freedom of choice of hospital.

(4, 7, 8) It is true that under S. 1161 all doctors are not required to be salaried employees of the government. Doctors employed under the scheme may be paid fees, or both salary and fees, as the Surgeon General directs. "All" doctors may not be a part of the system, but the coverage is so great that little if any practice is left for the doctor who does not wish to become a part of the system.

(5) There is no freedom of remuneration for the doctor. The Surgeon General has full authority to approve payments to practitioners according to a schedule of fees, or on a per capita basis, or on a salary basis for whole or part time, or a combination or modification of all these. The statute [ibid. sec. 905(7), p. 46] on its face appears to give the practitioner some freedom, but the ultimate authority is in the Surgeon General, as all payments are "subject to such necessary rules and regulations as may be prescribed" by the Surgeon General.

(6) Nor has the hospital any freedom with respect to remuneration. The Surgeon General [ibid. sec. 907(a), p. 49] with the approval of the Social Security Board determines the amount to be paid for hospitalization, varying from \$1.50 to \$6.00 per diem [ibid. sec. 915(g), p. 57].

(10) Voluntary hospitals are eligible, but subject to all the rules and regulations governing participating hospitals [ibid. sec. 907(a), p. 49; sec. 915(f)(g), pp. 56-57].

(11) Under our system of government and American way of life a plan of medicine directed from Washington would not "promote the personal relations between doctor and patient, and be adapted to the needs and practices of the individual community, and the wishes of the doctors in that community, in both rural and urban areas, . . ." It is inevitable that such a plan would seriously disturb the existing intimate relationship between doctor and patient.

(12) It is not correct that similar basic principles as to medical and hospital benefits and freedom of medical practices are embodied in a program recently put forward by the government of Canada, with the full accord of the Canadian Medical Association and the Canadian Hospital Council. The Dominion of Canada recognizes and respects its constitutional limitations. S. 1161 is utterly beyond the powers of Congress.

For Senator Wagner to compare his bill favorably with the proposed Canadian measure is not justified. The Canadian plan provides for the adoption by each province of a model bill which the Dominion has drafted for the guidance of the provinces in framing their legislation. The Canadian government has no constitutional power to impose such a plan. It only proposes the plan and extends a subsidy to the provinces

which adopt it. The question arises among the provinces whether or not the Dominion by this indirect procedure is not interfering with the autonomy of the provinces, by encroaching on the right given them under the British-North America Act to legislate as they see fit on matters of health.

Another fundamental difference between S. 1161 and the Canadian plan is in its administration. Under S. 1161 the entire plan is administered by one man from Washington. In each Canadian province the act would be administered by a commission appointed by the Lieutenant-Governor-in-Council. Its chairman must be a doctor of medicine. He would be its chief executive officer and would have supervision over all other officers appointed to carry out the work of the commission. His fellow members on the commission would be men or women representative of the various professions rendering service under the act, including hospitals, and of industrial workers, employers, agriculturists and such other groups as it may be deemed desirable to recognize. The chairman would devote his whole time to the work of the commission and would be its only salaried member. Other members would be paid a per diem allowance for attending meetings. All persons employed to conduct the work of the commission would rate as civil servants and must be appointed in the manner prescribed by the Civil Service Act.

Thus the system in the provinces is removed from over-all control from the seat of government and there remains to it all the elements of home rule.

The insured may select from the list of practitioners who have agreed to attend insured patients any one he wants as his medical adviser, subject only to the willingness of the latter to accept him as a patient. The total cost per annum would be \$250,000,000.²³ This figure is to be compared with approximately \$3,000,000,000 in this country.

MEDICAL SERVICE IN THE UNITED STATES AND THE EFFECTS OF THE MEASURE ON SUCH SERVICE

1. Under the medical care now provided in the United States the highest level of health and the lowest death rate ever known under similar conditions are being maintained.
2. There are being developed in this country and under our system of free enterprise many plans for providing adequate medical care without paying the price of socialized medicine. These include group and hospital insurance and Blue Cross plans under principles approved by the medical profession. The Blue Cross plan beginning in 1933 and now covering more than fifteen million people provides for the moderate means class, on which hospital bills fall heavily.
3. The indigent, who are most in need of free medical care, are not covered by S. 1161.
4. Forty-two per cent of the expenditures for hospital services and for doctors' services rendered hospital patients in 1942 were either tax supported or otherwise without cost to the patient and without recourse to federal regulation and control as proposed.
5. Of all like plans now in effect in foreign countries, none is comparable with the plan proposed by S. 1161 except the Russian system, which involves the complete socialization and regimentation of medicine. Such a pattern, if followed in this country, will inevitably produce a like result. The physician will become merely an unambitious federal employee or a politically ambitious doctor.
6. Contrary to assertions of the advocates of the measure, the plan covers practically the entire population of the United States except the indigent.
7. To safeguard a minimal percentage of the population which has difficulty in obtaining complete medical service, the bill would put all the people in a medical strait jacket under the supervision of the federal government for an alleged service which the vast majority either do not require or are able to provide for themselves.
8. The measure will inevitably lessen the interest of the physician in his patient as an individual and dull the incentive

to produce the best results. The patient will become the guinea pig supplied by the government as the excuse for the payment of subsidies to a controlled profession for its routine services. This would disturb the social order of which both are members and result in vital loss both to the community and to the doctor.

9. The measure will subject to bureaucratic control and supervision the intimate and confidential relationship between doctor and patient and make confidential information resulting therefrom available to employees of the government.

10. Medical education and training, which have attained an unequaled standard of excellence in institutions conducted under our system of free enterprise, would under S. 1161 be subsidized, regulated and controlled by government.

11. Within the past twenty years the center of medical progress has moved from Germany, Austria and England, which have adopted some form of state medicine and which previously served as centers of postgraduate medical education, to the United States, and we now find physicians and hospital administrators coming for guidance and inspiration to this country, where no form of state medicine is in effect.

CONCLUSION

The American Bar Association is limited to an expression of opinion and judgment with respect to those fields which relate to the administration of justice and which directly affect the safeguards and protection of the rights and liberties of the citizens of this country. Under normal circumstances, therefore, it is not the function of this association to attempt to influence substantive legislation by the Congress of the United States. But when under the pretext of the general welfare legislation is proposed in Congress which either inadvertently or with deliberate subtlety constitutes a direct attack on the rights and liberties of the citizens of this country, it becomes the duty of this association actively to voice its objections, a summary of which is as follows:

1. Local self government must be preserved in our federal system. State governments directly responsible to the will of the people are best adapted to exercise such supervisory control as may be instituted over the health and medical care of our citizens.
2. S. 1161 seeks to invest in the Surgeon General, who is not an elected servant of the people and who is not amenable to their will, the power arbitrarily to make rules and regulations having the force and effect of law which directly affect every home.
3. The measure furnishes the instrumentality by which physicians for their practice, hospitals for their continued existence and citizens for their health and that of their families can be made to serve the purposes of a federal agency.
4. The bill fails to safeguard the rights of patients, citizens, hospitals or doctors with respect to disputes arising or rights denied through the arbitrary or capricious action of one man.
5. The bill fails to provide for any appeal to any court from the action of the Surgeon General.
6. The vicious system whereby administrative officials judge without court review the actions of their subordinates in carrying out orders issued to them is extended in this bill to a point foreign to our system of government and incompatible with the adequate protection of the liberties of the people.
- The Constitution of the United States is designed to protect the citizens of this republic in the exercise of the rights of free men. The provisions of that instrument can be rendered impotent when our citizens, for the sake of an apparent immediate benefit, surrender to their government such direct control over their lives that government, by imposing a constant fear on them of having those benefits withheld or withdrawn, can compel from them obedience and subservience to its dictates.

Respectfully submitted,

W. E. STANLEY, Chairman,
WILLIAM LOGAN MARTIN,
CLEMENT F. ROBINSON.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Popular Medical Lectures.—The sixty-second course of popular medical lectures will be held at Lane Hall, Stanford University School of Medicine, San Francisco. The group will include the following speakers, all of San Francisco:

Dr. William H. Northway, Treatment of Infantile Paralysis, March 17.
Dr. Albert V. Pettit, Caudal Anesthesia in Obstetrics, March 31.
Nina Simmonds, Sc.D., Nutrition: One Factor in the Health Program, April 14.
Dr. Horace Gray, Psychologic Types and Marriage, April 28.

Special Service Fund.—The San Francisco County Medical Society has established a special service fund to assist service men and their families in case of need. The funds will be used not only to help returning members during their time of readjustment but to help wives, families and service widows at any time before peace comes. Any one knowing of the need of a member's family is asked to notify Dr. Dolrmann K. Pischel, San Francisco, chairman of the special service fund committee.

Hamilton Anderson Named Professor of Pharmacology.—Dr. Hamilton H. Anderson, recently returned on the S. S. *Gripsholm* from his position as professor and head of the department of pharmacology, Peiping Union Medical College, Peking, China, has been appointed professor of pharmacology at the University of California Medical School, San Francisco. The appointment, effective February 1, fills the vacancy that occurred when Chauncey Leake, Ph.D., resigned to become vice president and dean of the University of Texas Medical Branch, Galveston. Dr. Anderson graduated at the University of California Medical School in 1930 and served as a member of the staff until 1937, when he joined the Council on Medical Education and Hospitals of the American Medical Association. He resigned this position to accept the Rockefeller Foundation appointment as professor of pharmacology at Peking University.

CONNECTICUT

Yandell Henderson Dies.—Yandell Henderson, Ph.D., an authority on gases and professor of physiology emeritus, Yale University, New Haven, died in Scripps Memorial Hospital, La Jolla, Calif., February 18, aged 70. Dr. Henderson had been suffering from an intestinal ailment for a year.

State Society Plans New Home.—At a special meeting of the house of delegates of the Connecticut State Medical Society in December it was decided to establish a permanent home in New Haven. The trustees of the building fund are now working on the acquisition of properties that might be available for suitable headquarters.

DISTRICT OF COLUMBIA

Annual Graduate Course in Ocular Surgery.—The George Washington University School of Medicine will conduct its seventh annual postgraduate course in ocular surgery, pathology and orthoptics, April 24-29. The instructors in the pathology course will include Col. James E. Ash, M. C., U. S. Army, curator of the Army Medical Museum, Major Alfred Golden, M. C., A. U. S., Helenor Wilder and Lawrence Ambrogio. The orthoptics course will be conducted by Dr. William Thornwall Davis, Dr. Ernest A. W. Sheppard, Dr. Frank D. Costenbader, Louisa Wells, Mary E. Kramer, Dorothy R. Bair and Mildred Brown. Additional information may be obtained from Miss Wells, 927 17th Street N.W., Washington.

GEORGIA

Personal.—Joseph C. Bequaert, Ph.D., and Dr. Everett P. Veatch, Bolahun, Liberia, recently went by plane to Liberia to carry on six months' research on African sleeping sickness.

Full Professors at Emory.—Emory University School of Medicine, Atlanta, has conferred full professorships on:

Dr. Cosby Swanson, professor of dermatology.
Dr. William Walter Young, professor of neurology and psychiatry.
Dr. Madison Hines Roberts, professor of pediatrics.
Dr. Frederick G. Hodgson, professor of orthopedic surgery.
Dr. Milus K. Bailey, professor of urology.
Dr. Grady E. Clay, professor of ophthalmology.
Dr. James Calhoun McDougall, professor of otorhinolaryngology.

ILLINOIS

Society News.—Dr. Leon Unger, Chicago, will discuss "Allergies, Hay Fever and Asthma" before the Kankakee County Medical Society, Kankakee, March 14.—The Will-Grundy County Medical Society was addressed March 10 in Joliet by Dr. Newell C. Gilbert, Chicago, on "Rheumatic Heart Disease."

Chicago

Dr. Major to Address Medical History Society.—Dr. Ralph H. Major, Kansas City, Mo., professor of medicine and lecturer in the history of medicine, University of Kansas School of Medicine, will deliver a lecture in the assembly room of the Institute of Medicine of Chicago April 4 under the auspices of the Society of Medical History of Chicago. The subject of his illustrated address is "Hippocrates and the Island of Cos."

KANSAS

Personal.—Dr. Fred H. Rhoades, Hanover, has been appointed health officer of Washington County.—Dr. Orlin P. Wood, Marysville, was appointed health officer of Marshall County to succeed Dr. Enoch Schumann, Blue Rapids.

Health Department in New Home.—The Kansas City-Wyandotte County Health Department is now located in its new home at 619 Ann Avenue. The three story red brick building contains accommodations for administrative offices. On the second floor are quarters of the sanitarians and milk inspectors; the laboratory, clinic and health inspection rooms are housed in the basement. William H. Pickett, surgeon, U. S. Public Health Service Reserve, is director of health of the city-county health unit.

MASSACHUSETTS

Personal.—Dr. Robert B. Osgood, John B. and Buckminster Brown professor of orthopedic surgery emeritus, Harvard Medical School, Boston, was granted honorary fellowship in the Royal College of Surgeons of England at a ceremony in the British Embassy in Washington, November 8.

Tufts Alumni Dinner.—The annual meeting and dinner of the Tufts Medical Alumni Association will be held on March 29 at the Copley Plaza Hotel, Boston. The guest speaker will be Dr. Morris Fishbein, Chicago, editor of *THE JOURNAL*, who will discuss "Probable Changes in Practice of Medicine Harmful to Patient If Bills Now Pending in Washington Become Law." Other speakers will include Leonard Carmichael, LL.D., president of Tufts College, on "Our First Fifty Years as a Prelude to Greater Things," Dr. Alonzo K. Paine, Boston, president of the alumni association, Capt. A. Warren Stearns (MC), U. S. Naval Reserve, dean-on-leave, and Dr. Karl T. Phillips, Putnam, Conn.

MICHIGAN

Personal.—George B. Darling, Dr.P.H., who recently resigned as president and comptroller of the W. K. Kellogg Foundation, Battle Creek (*THE JOURNAL*, Nov. 27, 1943, p. 849) is now executive secretary of the committee on military medicine of the division of medical science of the National Research Council, Washington, D. C.—Dr. Roger V. Walker has been appointed a member of the Detroit Board of Health to succeed the late Dr. Frank A. Kelly.—Dr. James Milton Robb recently presented to the Wayne University College of Medicine, Detroit, a fund for the use of the Alpha Omega Alpha Scholarship and Lectureship Foundation.

MISSOURI

License Suspended.—The license to practice medicine of Dr. Leo J. Barken, University City, was suspended by the state board of health, January 24, for a period of two years. The suspension is based on the conviction of Dr. Barken in the federal court for violation of the Harrison Narcotic Act.

The Narr Fellowship Foundation.—The Frederick C. Narr Fellowship Foundation has been incorporated to carry on the activities of the late Dr. Narr in providing financial assistance to young medical students and interns. Dr. Robert Lee Hoffmann is president of the corporation, Dr. Fred B. Kyger treasurer and Dr. Oliver S. Gilliland secretary. Trustees are Drs. Robert C. Davis, Sam E. Roberts and Ira H. Lockwood, all of Kansas City. According to the *Weekly Bulletin* of the Jackson County Medical Society, a fund of \$2,000 now available will be augmented to continue Dr. Narr's activities. In 1923 Dr. Narr became head of the Williams Volker Laboratory of Research Hospital, Kansas City, a position he held until his death on Sept. 2, 1943. Because of his full time activity with the hospital he became chairman of the committee on residents and interns and in this capacity personally gave

financial assistance to these men to help place them in the proper position in the medical world. In many instances he lent money, signed notes of security and counseled. The new fellowship foundation will attempt to extend this work. The proformatum decree of incorporation of the foundation, effective January 31, states that the new group's purposes are:

To aid and assist medical students, interns, residents, fellows, in continuing the study of medicine and surgery, and the pursuit of any and all allied branches of the medical science and art, including research, by furnishing to such individuals, as a board of trustees held from time to time, designate gifts, loans or advances to pay tuition, or other expenses incurred by or for such individuals in the attendance of medical school, hospitals, and research institutions.

MONTANA

Personal.—Dr. Albert D. Brewer has resigned as city-county health officer of Bozeman and Gallatin County to become staff physician at the Montana State Tuberculosis Sanitarium, Deer Lodge.—Mr. Herbert T. Walworth, for three years director of the division of industrial hygiene, Montana Department of Public Health, Helena, has resigned to become industrial engineer of the Tennessee Department of Public Health, Nashville.

NEW YORK

Graduate Lecture on Tropical Medicine.—Morton C. Kahn, Ph.D., associate professor of public health and preventive medicine, Cornell University Medical College, New York, will lecture on "Mosquito Borne Diseases" before the Saranac Lake Medical Society, April 5, at Saranac Lake. The lecture is sponsored cooperatively by the state department of health and the state medical society.

New York City

Instruction in Tropical Medicine.—A course in certain aspects of tropical medicine will be conducted at the DeLamar Institute of Public Health, Columbia University College of Physicians and Surgeons, March 20-May 13. Additional information may be had from the institute at 600 West 168th Street, New York 32.

The Sixth Harvey Lecture.—John W. Oliphant, Surgeon, U. S. Public Health Service, division of infectious diseases, National Institute of Health, Bethesda, Md., will deliver the sixth Harvey Society Lecture of the current series at the New York Academy of Medicine on March 16. His subject will be "Jaundice Following Administration of Human Serum."

Personal.—Dr. Condict W. Cutler Jr., director of surgery at Goldwater Memorial Hospital on Welfare Island and an alumni trustee at Columbia University, has resigned to accept a commission as lieutenant colonel in the army medical corps.—Dr. Israel Leopold Glushak has been invited to open a reconstruction surgical clinic in connection with the private hospital of Dr. Manuel de la Pila Iglesias at Ponce, Puerto Rico. This clinic will devote a large portion of its services to the subnormal income groups in Puerto Rico, the territorial department of the government assuming the expense of their hospitalization, according to the *Journal of the Medical Society of the County of New York*.

Postwar Emergency Fund.—The Bronx County Medical Society has agreed to assess its members to promote the collection of funds to aid members returning from military service to reestablish their private practice in the postwar period of readjustment. The action was approved in a resolution passed by the society. The fund will be administered by a loan committee of the group and will be known as the Post War Emergency Loan Fund. It was decided further that at the end of a period of emergency, as determined by the society, the fund will be known as the general fund of the Bronx County Medical Society, to be used for purposes beneficial to the society as determined by a two thirds vote of the membership present at any society meeting.

NORTH CAROLINA

Hospital News.—The Guilford General and the Burrus Memorial hospitals, High Point, were merged recently under the name of High Point Memorial Hospital. The Burrus Memorial has been designated as the Boulevard Unit and the other as the Washington Street Unit. J. P. Richardson, administrator of the Burrus Memorial, is director of the combined unit, and W. R. Peters, business manager of the Guilford General Hospital, will become business manager of the new institution.

Dr. Tinsley Harrison Goes to Texas.—Dr. Tinsley R. Harrison, professor of medicine at Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, has been appointed dean of Southwestern Medical College of the South-

western Medical Foundation, Dallas, effective immediately. Dr. Harrison will also serve as executive professor of experimental medicine and professor of medicine. He graduated at Johns Hopkins University School of Medicine, Baltimore, in 1922. He is a past president of the American Society for Clinical Investigation and is now chairman of the Section on Experimental Medicine and Therapeutics of the American Medical Association. According to Mr. Mac F. Cahal, executive secretary of the foundation, additional temporary buildings will be constructed near the site of the projected medical center to house the department of experimental medicine. Additional professors and research workers will be employed for the new department. Dr. Donald H. Slaughter, Dallas, formerly acting dean of the medical college, will remain as dean of students.

OHIO

Personal.—Dr. John Sraile has resigned as superintendent of the Tuscarawas Valley Sanatorium, New Philadelphia, effective February 1, to become clinician for the Washington Tuberculosis Association at Seattle.

University News.—The Research Foundation at Ohio State University, Columbus, has made available grants of \$35,000 to the university to stimulate and foster research in the basic science; \$5,000 will be available for surgical and medical research.

OKLAHOMA

Society News.—The Pottawatomie County Medical Society was addressed on March 7 among others by Dr. Percy S. Pelouze, Philadelphia, on "Control of Gonorrhea from a Public Health Standpoint."—The Oklahoma City Internist Association sponsored a clinic at the University Hospitals on February 22.

Personal.—Dr. Felix T. Gastineau has been appointed acting director of the student health service at the University of Oklahoma, Norman, succeeding Dr. William A. Fowler, who has gone to the University of Arkansas, Fayetteville.—Anderson Nettleship, P. A. Surg., U. S. Public Health Service Reserve, Bethesda, Md., has been appointed associate professor of pathology at the University of Oklahoma School of Medicine, Oklahoma City.

OREGON

Tuberculosis Program.—X-ray equipment has been purchased with funds subscribed by the Oregon Tuberculosis Association, the city of Portland and Multnomah County, to be housed in a clinic which will be operated by the Portland City Health Department. When the program gets under way the clinic will supervise follow-up case finding among family contacts of the tuberculous persons found in the Portland area by the recently created state division of tuberculosis control.

University News.—The University of Oregon Medical School, Portland, has purchased the Portland Medical Hospital on Marquam Hill to use as a dormitory to house student nurses, in keeping with the provisions of the cadet nurse corps program. Dr. Matthew C. Riddle, associate professor of medicine, and Harry J. Sears, Ph.D., professor of bacteriology at the university, are studying tropical diseases in Central America as an aid to wartime medical instruction. Dr. Riddle flew directly to Central America, but Dr. Sears will spend two months in the Army Medical School, Washington, D. C., before proceeding to Costa Rica, Honduras and Guatemala.

RHODE ISLAND

Advisory Council on Health.—On February 5 Gov. J. Howard McGrath activated a thirty-five member state voluntary advisory council on health to carry on an overall survey of health facilities and needs of the state. The program is the result of a suggestion made recently by Dr. Emery M. Porter, past president of the Providence Medical Association, that a statewide survey be conducted by a nonpartisan, representative council. The suggestion of Dr. Porter to create a twenty-five member council by the state medical society was endorsed by the society, but it was agreed to acquiesce in allowing the governor to name the council which he suggested. Using Dr. Porter's outline as a basis, the governor has enlarged the list to include representatives of insurance, the veterans, pharmacy and osteopathy. The new council includes eleven doctors of medicine, including the state director of health and one doctor representing the state hospital association, a dentist, a nurse, an osteopathic physician, two representatives of veterans' organizations, two representatives of organized labor, two representatives of industry, three insurance representatives, one of the Blue Cross, one of private insurance and one of the state director of insurance, two

representatives of social agencies, two attorneys at law, one representative of pharmacy, two representatives of the state department of social welfare and five representatives of the public generally, including two clergymen, a banker and an executive secretary. Dr. Michael H. Sullivan, Newport, president of the state medical society, is chairman of the council, Dr. Elihu S. Wing, Providence, vice chairman and Mr. Glen Leet, state administrator of public assistance, department of social welfare, Cranston, executive secretary. Other members of the council include:

Frank J. Benti, president, Rhode Island State Congress of Industrial Organization, Providence.
 Frederick S. Blackall Jr., president, Taft-Pierce Mfg. Co., Cumberland.
 Rt. Rev. Msgr. Peter E. Blessing, Providence.
 Rev. Arthur H. Bradford, Pastor, Central Congregational Church, Providence.
 J. Austin Carroll, state commissioner of insurance, Providence.
 Thomas W. Clune, D.D.S., Cranston.
 Edward L. Coman, insurance executive, South Kingstown.
 Miss Nellie R. Dillon, R.N., president, Rhode Island District Nursing Association, Providence.
 Dr. John E. Donley, Providence.
 John E. Farrell, executive secretary, Rhode Island Medical Society, East Providence.
 Dr. Albert H. Jackvony, president, Providence Medical Association, Providence.
 Dr. Henry E. Gauthier, Woonsocket.
 Christopher Hopkins, president, Rhode Island State Branch, American Federation of Labor, Providence.
 Walter F. Farrell, president, Union Trust Co., Providence.
 Dr. John P. Jones, Wakefield.
 Ernest I. Kileup, president and treasurer, Davol Rubber Co., Barrington.
 Mrs. Susan V. Lamb, chairman of legislative committee, State Association of Local Directors of Public Welfare, West Warwick.
 Judge Edward L. Leahy, Director, State Department of Finance, Bristol.
 Arthur J. Levy, president, Providence Council of Social Agencies, Cranston.
 Robert O. Loosely, executive director, United War Fund, Providence.
 Dr. Edward A. McLaughlin, State Director of Health, Providence.
 Eugene U. Messier, State Department Commander, Veterans of Foreign Wars, Central Falls.
 Cornelius C. Moore, Attorney at Law, Newport.
 Alexander Pausley, D.O., Providence.
 Dr. Herman C. Pitts, chairman, medical economics committee, Rhode Island Medical Society, Providence.
 Dr. Dennett L. Richardson, president, Hospital Association of Rhode Island, Providence.
 W. Henry Rivard, Pharm.D., Dean, Rhode Island College of Pharmacy & Allied Sciences, Providence.
 Dr. Arthur H. Ruggles, superintendent, Butler Hospital, Providence.
 Stanley H. Saunders, executive director, Hospital Service Corporation of Rhode Island, Providence.
 Dr. Stanley Sprague, Pawtucket.
 Harold B. Tanner, attorney at law, Providence.
 George E. Withington Jr., commander, American Legion Department of Rhode Island, Providence.

SOUTH CAROLINA

Medical Society Buys House for Nurses' Home.—The Medical Society of South Carolina, the Charleston County Medical Society, as trustee under the will of Thomas Roper, has purchased a house on the corner of Calhoun Street and Ashley Avenue, newspapers report. The residence will be used as a supplementary nurses' home to assist in the government's program to accelerate the training of nurses for army, navy and civilian needs, as well as to care for the increase of patients at Roper Hospital, Charleston.

TEXAS

Appointments to Southwestern Faculty of Medicine.—New appointments to the full time faculty of Southwestern Medical College of the Southwestern Medical Foundation, Dallas, include:

Simon Edward Sulkin, Ph.D., formerly instructor in bacteriology and immunology at Washington University School of Medicine and director of the virus laboratory, St. Louis Health Division, associate professor of bacteriology.
 Dr. Atticus J. Gill, formerly assistant professor of pathology, University of Tennessee College of Medicine, Memphis, assistant in pathology.
 Robert Merrett Pike, Ph.D., formerly bacteriologist and assistant director of Bassett Laboratories, Cooperstown, N. Y., assistant professor of bacteriology.

Sixty-one students will be graduated from the new school on March 20.

Anderson Cancer Hospital Dedicated.—The M. D. Anderson Hospital for Cancer Research, Houston, was dedicated February 17. Dr. Ernst W. Bertner, acting director of the hospital, presided at the ceremonies, which included the following speakers:

Hon. Coke Stevenson, governor of Texas.
 John H. Bickett Jr., chairman, board of regents, University of Texas Medical Branch, Galveston.
 Col. W. B. Bates, board of trustees, M. D. Anderson Foundation.
 Homer P. Rainey, Ph.D., president, University of Texas.
 Hines Baker, chairman, development board, University of Texas.
 Chauncey Leake, Ph.D., vice president and dean, University of Texas Medical Branch, Galveston.
 Dr. Bowman C. Crowell, Chicago, associate director, American College of Surgeons.

Dr. Fred W. Stewart, acting director, Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York.
 Dr. Frank E. Adair, chief surgeon, Memorial Hospital.
 Dr. Lauren V. Ackerman, director, Ellis Fischel State Cancer Hospital, Columbia, Mo.
 Dr. Hugh H. Young, director, Brady Urological Institute, Johns Hopkins Hospital, Baltimore.
 Clarence C. Little, Sc.D., managing director, American Society for the Control of Cancer, New York.
 Hon. Otis Massey, mayor of the city of Houston.
 Dr. Charles S. Venable, San Antonio, president, Texas State Medical Association.

The hospital is located temporarily at 2310 Baldwin Avenue in the former home of the late Capt. James A. Baker. Activities at the new hospital were to start March 1. The project is financed jointly by the state of Texas and the M. D. Anderson Foundation. It will function under the direction of the University of Texas. It was initiated when the forty-seventh legislature created a Texas state cancer hospital and a division of cancer research under the control and management of the University of Texas. An appropriation of \$500,000 was made for the location, equipping and establishing of the hospital, half earmarked for building and equipment, the remainder for employing a staff and for research, study, experiments, treatment and maintenance. This appropriation was matched by a \$500,000 gift to the university by the Anderson Foundation to supplement the legislative funds available for building and equipment. In addition the foundation offered to provide a site for the hospital. Eventually the site will be in the medical center that is being projected for a 134 acre site adjacent to Hermann Park, which the foundation has purchased from the city of Houston. When the war intervened it was decided to use the former home of Captain Baker as a temporary location in order that the research work might be started. One hundred and twenty-five beds will be available in Hermann Hospital eventually, but for the time being only 25 hospital beds will be available there. The service will include a diagnostic center, to which any physician in the state can send questionable tissue for diagnosis, and a statewide necropsy service. Patients from all over the state will be admitted for treatment. Only those will be accepted who have a chance to be cured. Eventually the hospital will accept part pay and full pay patients as well as indigents, but until the program gets fully under way only indigents will be admitted. Admission of indigents will be on certification of their county judge after examination by a physician and after investigation by the social service staff of the hospital.

VERMONT

University News.—Bennett C. Douglass, Ph.D., professor of education at the University of Vermont, Burlington, recently conducted several conferences with the faculty of the college of medicine on teaching and teaching methods. Dr. Louis S. Goodman, professor of pharmacology and physiology at the medical school, lectured before the Northeastern County Medical Society, February 23, on "Recent Advances in Drug Therapy."

GENERAL

Special Society Election.—Dr. Rolla E. Dyer, Bethesda, Md., was chosen president-elect of the annual meeting of the American Society of Tropical Medicine recently and Dr. Wilbur A. Sawyer, New York, was inducted into the presidency. Other officers include Dr. Harold W. Brown, New York, vice president, and Dr. Joseph S. D'Antoni, New Orleans, secretary-treasurer. Col. Charles F. Craig, M. C., U. S. Army, retired, 239 West Lullwood Avenue, San Antonio, Texas, is the editor of the *American Journal of Tropical Medicine*.

Federation of American Societies.—The Federation of American Societies for Experimental Biology, by vote of the executive committee, will not hold an annual meeting in 1944. Through the medium of the *Federation Proceedings*, however, provision will be made for the publication of abstracts of papers which would have been presented if it had been feasible to hold such a meeting. Similarly provision will be made for the full publication of papers contributed to several symposiums. This arrangement corresponds to that which was made in 1943, when the annual meeting was canceled. It was announced that a meeting will be held in Cleveland May 8-10, 1945 unless some unforeseen difficulty arises. The federation is composed of the American Physiological Society, American Society of Biological Chemists, American Society for Pharmacology and Experimental Therapeutics, American Society for Experimental Pathology, American Institute of Nutrition and the American Association of Immunologists.

War Conference on Industrial Health.—A war conference on industrial health, comprising the 1944 annual meetings of several national organizations concerned with industrial hygiene, will be held at St. Louis May 9-14 in the New Jef-

erson Hotel. The National Conference of Governmental Industrial Hygienists will meet all day on May 9. The American Industrial Hygiene Association meetings will begin on May 10 and continue through the morning of May 11. The American Association of Industrial Physicians and Surgeons will start its sessions on May 11 with clinics and meet in the afternoon with the American Industrial Hygiene Association. The American Association of Industrial Nurses will hold sessions on May 12, 13 and 14. A banquet will be held on May 11 for all members of the four cooperating associations. The Industrial Hygiene Division of the U. S. Public Health Service will conduct a seminar for engineers and chemists engaged in industrial hygiene work in federal and state agencies May 4-8 in St. Louis preceding the conference. Additional information may be obtained from Senior Sanitary Engineer J. J. Bloomfield, chief, field operations section, Industrial Hygiene Division, U. S. Public Health Service.

International Medical Congress.—On February 17 and 18 at a meeting in Laredo, Texas, the International Medical Congress was organized with Dr. Ismael Cosío Villegas, Mexico, D. F., president; Dr. Isidore S. Kahn, San Antonio, Texas, vice president; Dr. Norman Shafer, San Antonio, secretary, and Miss Pansy Nichols, Austin, executive secretary. The organization was the result of a meeting called to hold an international congress under the auspices of the Southwest Texas District Medical Society, the Texas Tuberculosis Association, the National Tuberculosis Association and the U. S. Public Health Service and the Pan American Sanitary Bureau. Local hosts were the Webb-Zapata-Jim Hogg Counties Medical Society and the Webb County Tuberculosis Association. The meeting was intended to bring together United States and Mexican physicians for discussions of medical subjects of interest to the medical profession in the border states of both countries. Among the speakers were:

Dr. Julius L. Wilson, New Orleans, What Modern Medical and Surgical Treatment Offer the Tuberculous Patient.

Dr. John G. Young, Dallas, Recent Advances in Infant Nutrition.

Dr. Alvis E. Greer, Houston, The Campaign Against Socialization of Medicine.

Dr. Percy S. Pelouze, Philadelphia, Modern Treatment of Gonorrhea.

Herman E. Hilleboe, P. A. Surg., U. S. Public Health Service, Community Control of Tuberculosis.

Dr. Miguel Jimenez, Mexico City, Collapse Therapy in the Control of Tuberculosis.

Eighty-two physicians registered at the meeting, fifty-nine of the United States and twenty-three of Mexico. It was agreed to hold a similar congress annually in Laredo.

Refrigeration Research Foundation.—An initial fund of \$250,000 will be used to start the work of the Refrigeration Research Foundation, a non-profit making corporation organized under Illinois laws Oct. 14, 1943. Membership in the new foundation is composed of two groups—public members who have achieved civic distinction and sustaining members, representatives of companies who have contributed funds to the foundation. Funds will be provided by subscriptions from corporations, firms or individuals engaged in the preservation of food or other commodities by refrigeration. Research will be carried on in Canada and Mexico as well as in the United States. The objectives of the new group are:

To improve the methods of refrigeration for the better preservation of food and other commodities essential to the health and welfare of the American people.

To develop and support research in the science and art of refrigeration of food and other commodities through a nation-wide program of financial grants to established institutions and agencies of research.

To establish fellowships in institutions and agencies of research and thereby to aid in the training of competent personnel to give activation and leadership to the refrigeration of commodities essential to the national economy.

To establish in the interest of the American people a repository of scientific information relating to the refrigeration of food and other materials.

To cooperate with and aid agencies of federal and state governments, institutions of research and others in connection with their scientific and educational work involving the refrigeration of food and other products.

Officers include Roy M. Hagen, Los Angeles, president, and Helmut C. Diehl, B.S., principal chemist and chief of the commodity processing division of the Western Regional Research Laboratory of the U. S. Department of Agriculture, director of the scientific program.

LATIN AMERICA

Health Activities in Latin America.—The Cuban Ministry of Agriculture is assisting Dr. B. Vaillant Duany in his studies after his recent discovery of a bacterial mold while investigating the penicillium fungus. The name *Broomeya cubensi* has been given to the new mold, which is said to be characterized by a kidney shaped form of 20 to 30 cm. in circumference and having a sponglike texture. In the report released to the ministry, it is stated that from the industrial point of view this fungus might well replace marine sponges, since its absorbent powers are absolute. Its texture is not

disintegrated by alcohol and it embodies all other properties of sponges. The report continues that in surgery the material could be substituted for the cotton and gauze sponges and that it may be used in the treatment of certain ulcerous diseases, serving as a pressure absorber for bandages. The cultivation of the fungus is best obtained in shaded beds of silica and other soil with a 70 per cent organic content, it was stated.

Blood Banks.—The Cuban Medical Federation has established a blood plasma bank in Havana, the first in a series to be formed throughout the country. The work is being carried out with the assistance of Dr. Cornelius P. Rhoads of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, who recently made a trip to Cuba's medical centers under the auspices of the National Research Council.

Mother's Milk Bank.—The Infant Hygiene Department of Havana has created a mother's milk bank.

Care of Rubber Workers.—Five dispensaries have been opened in northwestern Ecuador for rubber workers, bringing to a total of seventeen the number now operating in this rubber area through the cooperation of the Ecuadorean government and the Institute of Inter-American Affairs, Washington. Each dispensary is staffed by a physician trained in tropical disease control and usually a laboratory technician. The new dispensaries are at Tena, province of Napo and Pastaza; Concepcion, province of Esmeraldas, and in Cojimes, Coaqui and Jama in the province of Manabi.

New Medical Journal.—*Revista Brasileira de Medicina*, a new monthly publication, made its appearance with the January issue. The first number contains sections of original articles, medical lectures, clinical notes, critical commentaries, current medical literature, medical news and books received. Dr. Olavo Rocha is the editor. The headquarters of the new journal are Editora Guanabara, rua do Ouvidor 132, Rio de Janeiro.

FOREIGN

Personal.—Dr. Andrew Rae Gilchrist was appointed George Alexander Gibson Lecturer for 1944 for the Royal College of Physicians of Edinburgh and Dr. Norman M. Dott was appointed Morison Lecturer. Both are members of the college. —Dr. William H. Newton, since the outbreak of war acting head of the department of physiology at University College, London, has been appointed George Holt professor of physiology in the University of Liverpool, succeeding Dr. Herbert Eldon Roaf, who is retiring at the end of March. —Dr. George Grey Turner, professor of surgery in the University of London, has been elected to deliver the Hunterian oration for 1945 of the Royal College of Surgeons of England.

Medical Changes in Norway and Sweden.—From a personal letter comes the following information regarding medical conditions in Norway and Sweden. An eminent physician writes: "Here in Sweden the conditions are still quiet. We live very nearly as in the deepest peace with the exception that we are using all means to strengthen our defenses in the hope to keep us free from German attacks. Dr. Gunnar Holmgren, widely known as an authority on laryngeal cancer, has discontinued his service as professor and clinical chief of the otorhinolaryngologic department in the Karolinska Sjukhuset because of age. His successor is Dr. Torsten Skoog. Dr. Dohlman is professor in Lund, and Dr. Nylen is professor in Uppsala. Professor Blegvad has been ill but has made an excellent recovery. The clinic of De Kleyn in Holland is still endeavoring to conduct some scientific research in spite of the terrific circumstances that prevail. Professor Schmiegelow in Copenhagen has just celebrated his 87th birthday and is reported still able to work. In Norway scientific research in medicine seems to have been discontinued completely owing to prevailing circumstances."

Deaths in Other Countries

Dr. Alexander Primrose, professor of clinical surgery emeritus, University of Toronto Faculty of Medicine, died February 8, aged 82. Dr. Primrose, who was an honorary fellow of the American Medical Association, once served as dean of the University of Toronto. —Dr. Heitor Annes Dias, professor of clinical medicine in the Faculty of Medicine of Rio de Janeiro for many years, died recently.

CORRECTION

Tables of Approximate Equivalents of Doses, Apothecaries' and Metric Systems.—In THE JOURNAL, February 19, page 509, in the abbreviated conversion table, for "1 grain = 0.648 gram (Gm.)" substitute "1 grain = 0.0648 gram (Gm.)."

Sex Education

In recent years there has been a growing sense of the need for young people to be suitably introduced to and instructed in the matter of sex and of the responsibilities of schools and youth organizations in this work. This need is increased by the tendency of wartime circumstances to break down restraints. The Board of Education has therefore issued a pamphlet on sex education in schools and youth organizations. Up to the present time such instruction has not been generally undertaken by the board, which now invites the particular attention of local authorities to two practical possibilities: 1. The provision of short courses on sex education for teachers and youth leaders to open up the subject and make available the experience of colleagues who have pioneered successfully in this field and others who have had special knowledge and experience. 2. The organization of parents' meetings with a view to securing their cooperation in anything done through the schools and helping them to deal with their own children. These suggestions relate primarily to the long-term aspect of sex education. But in certain areas authorities are now much exercised by the immediate problem of the increased number of young persons who fall victims to the special temptations and circumstances of wartime.

It is pointed out that knowledge of the process of human reproduction comes to every one sooner or later but that the way in which this knowledge is acquired is all important. The first approaches to the subject are probably best made not through formal instruction but by dealing sensibly with any question asked. Whatever the age and whatever the question, the answer should be given to the fullest extent that the child can understand. A substantial proportion of parents are reluctant to do this or feel the need of some guidance. Hence the for instruction in school. During the war many young have become victims of indiscriminate associations, with increasing incidence of venereal disease. It is important that they should be warned of the danger, though it is undesirable that sex instruction should be concentrated on the pathologic aspect.

Instruction in the physiology of sex should be given objectively at an early age, before emotional associations develop and if possible as part of a normal course in, for example, biology or general science. When the child is more mature the teacher will draw on his or her own experience of life, or the religious and moral sources on which he or she has relied. How the sex impulse can make or mar happiness should be shown then.

The age at which sex instruction is given varies considerably. The most common age is 13, the last year at school and the stage at which mammals and man are most often discussed in the biology course. But it is increasingly realized that there are great advantages in introducing the subject at an early age, before strong emotional associations develop. Physicians have an obvious advantage for sex instruction, as they can speak with authority. The following testimony from a girls' organization is noteworthy: "A really good woman physician, preferably married, youngish, with a modern approach and modern clothes, is the most successful. The girls trust the physician as a physician and welcome her counsel as a married woman; she looks like the sort of woman they would like to be." Appre-

ciation from parents regarding this work has been expressed almost universally, and among its most valuable results is the possibility that these children, when they become parents, will find it easier to give this knowledge to their own children.

American Army Takes Over Military Hospital

An impressive ceremony took place recently when a famous military hospital was handed over to the medical services of the United States for the duration of the war. The locality of the hospital is not published. The hospital contains many memorials of past senior officers whose lives were spent in the medical services of the army all over the empire. When Lieut. Gen. Sir Alexander Hood, director general of the Army Medical Service, and Brig. Gen. Paul R. Hawley, chief surgeon of the U. S. forces, reached the parade ground they were received with a general salute from the troops of the two nations. After inspection of the guard of honor the party ascended the main entrance steps. Here the registrar of the hospital, who has fifty-one years of army service and is the oldest soldier serving in the army medical corps, handed the presentation key, which lay on a cushion bearing the badges of the medical services of both armies, to Sir Alexander Hood, who said "I hand over this key in the certain confidence that when in the hour of victory we receive back the hospital its traditions will have gained an added luster." The key was received by Brigadier General Hawley, who said that he accepted the charge of the hospital so generously placed at their disposal and assumed the obligation of maintaining its great traditions. He added "The final symbol of our association can be found in this hospital."

Trinidad Health Campaign: Improvements Achieved

The Colonial Office announces that \$2,500,000 is to be spent on Trinidad's health program this year, which is \$500,000 more than was spent last year. New specialists in the hospitals, higher salaries for nurses and a new health education officer to supervise the teaching of hygiene in the schools are among the improvements envisaged. Work on two new hospitals may be held up till after the war, but it is hoped that construction of the \$1,500,000 tuberculosis sanatorium may start this year. Two new health centers have been built and the first rural dispensary is in course of construction. A child welfare center established last year is proving successful. Campaigns against disease have made gradual but steady progress. Antimalarial measures have included the clearing of swamps, and one cleared on the sea-shore promises to become a popular health resort.

The incidence of typhoid and dysentery has declined. A vigorous campaign against hookworm is being carried out. Two mobile hookworm units are now supplementing the work of clinics in rural areas. The medical superintendent at the Trinidad Leprosarium has been responsible for many improvements; district clinics throughout the island now deal with many early cases of leprosy, rendering transfer to the leprosarium unnecessary.

Turkish Medical Visitors

The war seems to have brought to this country many medical visitors from almost all allied and neutral nations. The latest arrivals are three leaders of the Turkish medical profession whose visit is sponsored by the Turkish Ministry of Health. They are Dr. Huseyin Avni Askel, chief surgeon to the Haskei Hospital, Istanbul; Lieut. Col. Burhanettin Tugan, professor of clinical chemistry, Gulhane Military Medical School, and member of the Military Medical Academy, and Dr. Bekir Nimetullah Taskiran, chief surgeon of the Ankara Model Hospital. They are interested in research work on nutrition, wartime surgery, methods of blood transfusion and the treatment of wounds, burns and other injuries.

BRAZIL

(From Our Regular Correspondent)

Jan. 20, 1944.

Identity of the Equine Encephalomyelitis Virus
in Brazil and the United States

Up to a few months ago, little was known about the cause of equine encephalomyelitis in Brazil. For the other countries of South America Rosenbusch and Howitt proved that a virus isolated in Argentina was indistinguishable from the western strain of the United States, and Beck, Wyckoff, Kubes and Rios affirmed that a virus isolated in Venezuela was antigenically distinct from both the eastern and the western American strains. In Brazil Carneiro in 1937 isolated a virus which he supposed "very similar to that of the infectious encephalomyelitis of the United States" as far as clinical and pathologic data from inoculations in experimental animals could show. More recently, with a formaldehyde treated vaccine prepared from the same virus, Carneiro was able to protect guinea pigs inoculated intracerebrally with an homologous virus. Nevertheless, as he could not show the existence of cross immunity between the virus isolated by him and that from Argentina, the Brazilian virus continued unidentified. Owing to uncertainty in the identification of the several infectious agents isolated from cases of equine encephalomyelitis in Brazil, it is interesting to record the fact that Drs. Edwin H. Lennette and John P. Fox of the Service of Studies and Researches on Yellow Fever, maintained in cooperation by the International Health Board of the Rockefeller Foundation and the Brazilian Ministry of Health, have been able in the Rio de Janeiro laboratory to find horses and mules with antibodies neutralizing the eastern strain of the equine encephalomyelitis virus of the United States.

Not long ago an epizootic of encephalomyelitis occurred in the county of Pessanha, located in the east central part of the state of Minas Geraes. Samples of serum were collected from 18 horses and mules which had passed through the epizootic. These serums were first tested for neutralizing antibodies to the St. Louis encephalitis, a sample furnished by Dr. M. G. Smith of Washington University, St. Louis, being used, and then for neutralizing the eastern and western strains of the equine encephalomyelitis virus, through the use of samples furnished by Dr. P. K. Olitsky of the Rockefeller Institute, New York. None of the serums contained demonstrable antibodies to the St. Louis or the western equine encephalomyelitis viruses. Fourteen of the 18 serums, however, possessed antibodies to the eastern strain. Only one of the 20 control serums obtained from adjacent areas was found to contain antibodies to the eastern strain of the virus, and this one also came from the county of Pessanha. The conclusion of this study is that the eastern strain of the equine encephalomyelitis virus occurs also in Brazil and is not confined to North America.

A New Ponderal Test for Detection of the
Activity of Adrenal Cortex Extract

Unilateral adrenalectomy causes apparent hypertrophy of the remaining gland, as shown by the MacKays. In normal animals adrenal extract induces atrophy of the adrenal glands, a phenomenon demonstrated by Ingle and Kendall. The growth stimulus seems to be dependent on the adrenotropic hormone of the hypophysis. The MacKays demonstrated that active cortical extracts are able to prevent the pituitary stimulus in adrenalectomized rats. Based on these findings, Dr. Gilberto G. Villela of the Oswaldo Cruz Institute of Rio de Janeiro devised a new biologic test: The weight of the remaining adrenal glands of the rats is taken as a criterion for the activity of the cortical extracts injected. Rats weighing from 20 to 60 Gm. were employed. Adrenalectomy was performed unilaterally, and

the extract was injected from the same day until the eighth day after operation. At this time the second gland was removed, dried and weighed. For each test three groups of rats were used, the first group having been injected with the unknown extract, the second with 0.5 mg. of 11-desoxycorticosterone, and the third not injected. The weight of the adrenals of the rats of the third group showed definite hypertrophy compared with the other groups. The weight and size of the glands of normal rats of the same age showed values comparable to those of the rats which were operated on and injected with active extracts or 11-desoxycorticosterone. When younger rats weighing from 20 to 30 Gm. were used the differences were not as evident as when older animals, weighing from 50 to 60 Gm., were employed. The quantity of the hormone necessary to maintain the weight of the gland of the adrenalectomized rat at the same level as the weight of the gland of the rat which is not operated on is proposed as "1 antihypertrophic rat unit."

Brief Items

Dr. Alfredo da Matta of Manaus, state of Amazonas, has just completed fifty years in the practice of medicine. As a physician and as a citizen Dr. da Matta has an exceptional record, and for this reason the Medical Society of Manaus, the government and his many friends have held several demonstrations in his honor.

The Brazilian Academy of Medicine of Rio de Janeiro rewarded the monograph of Drs. Cicero Monteiro and Candido de Oliveira on "Tumors of the Neck" with the prize "Hilario de Gouveia." Dr. Aloysio de Castro, professor emeritus of medicine of the University of Rio de Janeiro and president of the academy, presented a special medal to the authors.

In a farm near Agua Claras, state of Bahia, a "preventorium" for 100 healthy children of leprosy parents has been recently inaugurated. This is the sixteenth such establishment founded by the federal government in the last few years. There are about 30,000 persons with leprosy in Brazil, many of them isolated in fifteen leprosariums built since 1935, when the federal government began to put into practice a large plan to control the disease.

Marriages

JOHN GARNETT RAMSBOTTOM, Jamaica, N. Y., to Miss Harriet Louise Strayhorn of Durham, N. C., in Cheraw, S. C., December 30.

ROBERT HOWELL WITMER, Lancaster, Pa., to Miss Audrey Elizabeth Bickley of Bala-Cynwyd, December 27.

PAUL ALOYSIUS KEENEY, Harrisburg, Pa., to Miss Ann Fitz Gerald of Flushing, N. Y., December 17.

WILLIAM WALTER LEMAN, Philadelphia, to Miss Ruth Cordelia Staley of Haverford, Pa., December 18.

LYNDON CLAY SUTHERLAND, Springfield, Ohio, to Miss Ruth Anne Vogel of Waukegan, Ill., February 5.

JULIAN EDMOND JR., Modesto, Calif., to Miss Elizabeth Bonine of Lodi at Stockton in January.

ROBERT EDWIN SHIFLET, Augusta, Ga., to Miss Helen Marie Crisp in Seneca, S. C., December 29.

ORHO B. ROSS JR., Charlotte, N. C., to Miss Dorothy Maude Lowe of Miami, Fla., December 22.

EDWARD D. CROISSANT, Belmont, Mass., to Miss Frances Sisk of Houston, Texas, January 28.

WARREN H. ORR, Seattle, to Miss Opal MacCulloch of Providence, R. I., January 1.

EDGAR ANGEL to Miss Maybelle Bryant, both of Franklin, N. C., January 18.

DAVID GALLOWAY to Miss Alice Neil, both of Memphis, Tenn., January 5.

S. MARK WHITE to Mrs. Jewell Fuller, both of Minneapolis, January 22.

Deaths

Charles Walts Burr ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1886; professor of mental diseases at his alma mater from 1901 to 1931 and since the latter date professor emeritus; emeritus professor of neurology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; president of the American Neurological Association in 1908 and the Philadelphia Psychiatric Society in 1909 and 1910; past president of the Philadelphia Neurological Society and the Pathological Society of Philadelphia; member of the American Psychiatric Association; fellow of the American College of Physicians; neurologist from 1896 to 1931 and psychiatrist at the Philadelphia General Hospital from 1931 to 1940; for many years on the staff of the Philadelphia Orthopaedic Hospital and Infirmary for Nervous Diseases; delivered the S. Weir Mitchell Oration before the College of Physicians of Philadelphia Nov. 19, 1919; honorary librarian, College of Physicians of Philadelphia; in 1935 received the twelfth annual Strittmatter Award of the Philadelphia County Medical Society; died February 19, aged 82, of carcinoma of the pancreas.

Myron Firth Metzenbaum ☉ Cleveland; University of Wooster Medical Department, Cleveland, 1900; specialist certified by the American Board of Otolaryngology; a member of the founders group of the American Board of Plastic Surgery; member of the American Academy of Ophthalmology and Otolaryngology, Cleveland Otolaryngological Club, Academy of Medicine of Cleveland and the European Congress of Reconstructive Surgery; fellow of the American College of Surgeons; awarded medal by the United States government for research in radium, St. Louis Exposition in 1904; established Cleveland's present ambulance system under police department in 1909, which was adopted throughout the country; developed and introduced the method of administering ether-air or drop ether anesthesia in 1900; described a new method of replacement of the lower end of the dislocated septal cartilage in 1929; at one time lecturer at the Western Reserve University School of Medicine; served on the staffs of the Huron Road Hospital, East Cleveland, Mount Sinai and St. Luke's hospitals; died January 25, aged 67, of angina pectoris.

James Lung Bevans ☉ Colonel, U. S. Army, retired, Vashington, D. C.; Northwestern University Medical School, Chicago, 1893; fellow of the American College of Surgeons; entered the medical corps of the U. S. Army as an assistant surgeon on Dec. 6, 1901; rose through the various grades to that of lieutenant colonel on May 15, 1917; retired Aug. 21, 1922 for disability in line of duty; promoted to colonel on June 21, 1930 under a special act; veteran of the Spanish-American War; chief surgeon of the Third Army Corps in France during World War I and later assistant commandant of the medical department, Field Service School, Carlisle, Pa.; held the Distinguished Service Medal and the Croix de Guerre with Palm; in 1920 received the Henry S. Wellcome Medal for the best essay on medicomilitary subject; served as the first director and medical superintendent of the John D. Archbold Memorial Hospital, Thomasville, Ga.; died in the Walter Reed General Hospital February 5, aged 74, of congestive heart disease.

Hugh Alvin Cowing ☉ Muncie, Ind.; Miami Medical College, Cincinnati, 1890; past president and vice president of the Indiana State Board of Health; for many years secretary of the Delaware County Board of Health; president of the city board of health; served as city and county health officer; past president and secretary of the Delaware County Medical Society; one of the organizers, served as director, vice president and president of the Y. M. C. A.; a member of the Indiana State Committee of the International Congress on Tuberculosis in 1908; for many years president of the Delaware County Children's Home Association; formerly vice president of the Muncie Federal Savings and Loan Association; member of the Selective Service Board, 1917-1918, and the Volunteer Medical Service Corps in 1918; author of "A Meandering Hoosier" in 1937; member of the staff and vice president of staff 1932-1933, Ball Memorial Hospital, where he died February 9, aged 83, of carcinoma of the prostate with metastasis.

George Washington Post ☉ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; president of the Illinois State Medical Society; president of the Chicago Medical Society, 1937-1938; fellow of the American College of Surgeons; formerly assistant in surgery at his alma mater, now known as the University of Illinois College of Medicine, instructor in clinical surgery, associate in surgery, assistant professor of

surgery, and since Sept. 1, 1930 associate professor of surgery; member of the founders group of the American Board of Surgery; formerly consulting surgeon, Chicago State Hospital; attending surgeon, West Suburban Hospital, Oak Park, Ill.; at one time attending surgeon, St. Anne's Hospital; died, March 2, aged 59, of coronary occlusion.

Caleb Anderson Ritter ☉ Kansas City, Mo.; Indiana Medical College, Indianapolis, 1877; an Affiliate Fellow of the American Medical Association; member of the Central Association of Obstetricians and Gynecologists; past president of the Kansas City Academy of Medicine; fellow of the American College of Surgeons; formerly a trustee, treasurer and professor of obstetrics at the University Medical College; at one time city physician and police surgeon in Indianapolis; served on the staffs of the Florence Crittenton and St. Vincent's maternity homes, the University Hospital, Kansas City General Hospital, Research Hospital, Christian Hospital, Willows Maternity Sanitarium and the Trinity Lutheran Hospital, where he died January 31, aged 92, of bronchopneumonia.

Harry S. Berman ☉ Detroit; College of Physicians and Surgeons, Baltimore, 1914; specialist certified by the American Board of Pediatrics, Inc.; a captain in the medical corps of the U. S. Army during World War I, served on former President Hoover's food commission and aided in the rehabilitation of Czechoslovakia; secretary-treasurer of the Wayne County Medical Milk Committee; member of the Association of Military Surgeons of the United States and American Public Health Association; member of the child welfare division of the American Relief Administration; on the staff of St. Mary's Hospital; member of the selective service examining board and on the staff of Harper Hospital, where he died February 16, aged 54.

Philip Davie Kerrison, New York; Medical College of the State of South Carolina, Charleston, 1896; New York University Medical College, 1898; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society and the American Otological Society, Inc.; fellow of the American College of Surgeons; formerly clinical lecturer on diseases of the ear at the University of Bellevue Hospital Medical College; served as professor of otology at the New York Polyclinic Medical School; for many years on the staffs of the Willard Parker and Manhattan Eye, Ear and Throat hospitals; author of "Diseases of the Ear"; died January 24, aged 82, of heart disease.

William Wallace Roblee ☉ Riverside, Calif.; Cooper Medical College, San Francisco, 1895; past president of the California Medical Association and the Riverside County Medical Society; member of the House of Delegates of the American Medical Association in 1937; veteran of the Spanish-American War and World War I; served as physical director and director of the local Y. M. C. A. and president of the association for many years; formerly associated with the Indian Service; on the staffs of the Sherman Institute Hospital and the Riverside Community Hospital, where he died January 24, aged 71.

Major Henry Worthington ☉ Chicago; Northwestern University Medical School, Chicago, 1901; since 1930 medical superintendent of the Research and Educational Hospitals, University of Illinois; served as assistant eye surgeon at the Illinois Charitable Eye and Ear Infirmary, assistant in ear, nose and throat department, Chicago Eye, Ear, Nose and Throat Hospital and Rush Medical College Dispensary, and assistant in eye department, Children's Memorial Hospital; at one time secretary of the Chicago Ophthalmological Society; died February 27, aged 64, of coronary thrombosis.

Edwin F. Arnold, Bellefontaine, Miss.; Memphis (Tenn.) Hospital Medical College, 1891; member of the Mississippi State Medical Association; for many years chairman of the Webster County Democratic Executive Committee; trustee of the Eupora special consolidated school district and director of the Bank of Eupora; died January 7, aged 73, of cerebral hemorrhage.

Paul Bradford Badger Jr., Greenwich, Conn.; Columbia University College of Physicians and Surgeons, New York, 1943; died December 12, aged 26, of an overdose of sedative, self administered.

Cheney Hosmer Calkins, Springfield, Mass.; University of Pennsylvania Department of Medicine, Philadelphia, 1882; member of the New England Ophthalmological Society; died January 19, aged 83, of cerebral thrombosis due to generalized arteriosclerosis.

Jay Randolph Crawley ☉ Anjean, W. Va.; Ohio State University College of Medicine, Columbus, 1917; served during World War I; died in a hospital at Charleston February 2, aged 52, of heart disease.

William Moody Cunningham * Jasper, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1884; member of the House of Delegates of the American Medical Association, 1926-1927; past president of the Medical Association of the State of Alabama, the Walker County Medical Society and the Southern Railway Surgeons Association; a founder of the Corona Hospital, Corona; served on the staffs of the Peoples and Walker County hospitals; died in Birmingham January 18, aged 85, of heart disease.

John O. Dyrnes * Manasoa, Benenitra, Madagascar, Africa; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1897; Associate Fellow of the American Medical Association; a medical missionary under the auspices of the American Lutheran Free Church Mission; died December 7, aged 76, of diabetes mellitus.

Orville Reed Hagen, Paterson, N. J.; Columbia University College of Physicians and Surgeons, New York, 1905; member of the Medical Society of New Jersey; a director and past president of the Passaic County Tuberculosis and Health League; served as a major in the medical corps of the U. S. Army and with the American Expeditionary Forces in France during World War I; formerly city health officer; on the staffs of the Valley View Sanatorium and the Paterson General Hospital; died January 23, aged 64, of coronary occlusion.

Virgil Hammer, Luray, Va.; Medical College of Virginia, Richmond, 1901; served as coroner and health officer of Page County for many years; died January 18, aged 66, of organic heart disease and coronary thrombosis.

Joel Walter Hood, Ocala, Fla.; Hospital College of Medicine, Louisville, Ky., 1884; honorary member of the Florida Medical Association; served for a short time during World War I; died recently, aged 92.

Theodore James Kasinski, Lorain, Ohio; Ohio State University College of Medicine, Columbus, 1916; served during World War I; died in the Veterans Administration Facility, Chillicothe, January 12, aged 54, of arteriosclerotic heart disease.

Elizabeth Kendig, Lancaster, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1886; died January 9, aged 89, of chronic myocarditis.

Hermann Loeb, Bridgton, Maine; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1906; died January 27, aged 62, of cerebral hemorrhage.

William Edward MacCoy, Glendale, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; died January 6, aged 68, of coronary disease.

Howard Peter Mickley, Neffs, Pa.; Jefferson Medical College of Philadelphia, 1889; died in the Allentown Hospital, Allentown, January 8, aged 77, of diabetes mellitus.

Harry Miller, Morristown, Ind.; Medical College of Indiana, Indianapolis, 1891; for many years served on the staffs of the National Home for Disabled Volunteer Soldiers at Marion, and Danville, Ill.; died January 2, aged 76, of cerebral hemorrhage.

William Francis Monaghan, Philadelphia; Medico-Chirurgical College of Philadelphia, 1899; formerly on the staff of the Misericordia Hospital, where he died January 10, aged 70, of lung abscess and myocarditis.

James Joseph Moran * Spring Valley, Ill.; Northwestern University Medical School, Chicago, 1905; past president of the Bureau County Medical Society; past president of the Hall township high school board; senior surgeon, St. Margaret's Hospital, where he died January 20, aged 67, of splenic anemia (familial type).

James Munsie, Cleveland Heights, Ohio; Niagara University Medical Department, Buffalo, 1898; served on the staff of the Hospital Clinic, now the Polyclinic Hospital, in Cleveland; died in the Woman's Hospital, Cleveland, January 18, aged 76, of leukemia and pneumonia.

Jay Odell Nelson, Howard City, Mich.; College of Physicians and Surgeons, New York, 1890; served as president of the school board and health officer; died January 13, aged 80, of pneumonia.

John Nugent, Southampton, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881; served as coroner of Suffolk County and for many years health officer of Southampton; a founder of the First National Bank of Southampton and for many years president; on the staff of the Southampton Hospital; died January 18, aged 85, of cerebral hemorrhage.

Louis Ely Papurt * Cleveland; Western Reserve University School of Medicine, Cleveland, 1924; specialist certified by the American Board of Orthopaedic Surgery, Inc.; mem-

ber of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served on the staffs of the Lutheran Hospital, St. John's Hospital, Fairview Hospital, Deaconess Hospital, St. Luke's Hospital and the Mount Sinai Hospital, where he died February 17, aged 43, of rheumatic heart disease.

Mary Almera Parsons, Washington, D. C.; Howard University College of Medicine, Washington, 1874; member of the Medical Society of the District of Columbia; died in St. Elizabeth Hospital January 12, aged 93, of coronary occlusion and arteriosclerosis.

John Green Pittman, Gaffney, S. C.; Columbia University College of Physicians and Surgeons, New York, 1900; member of the South Carolina Medical Association; formerly secretary of the Cherokee County Medical Society; served as president of the board of health; on the staff of the Cherokee County Hospital, where he died January 7, aged 68, of coronary thrombosis.

Elgen Clayton Pratt * Lieutenant Colonel, U. S. Army, retired, Plymouth, Wis.; Milwaukee Medical College, 1908; U. S. Army Medical School, 1923; entered the medical corps of the U. S. Army on July 1, 1920; promoted as a major on Sept. 4, 1930 and later as a lieutenant colonel; retired Sept. 30, 1938; served during World War I; died December 29, aged 59, of coronary embolus.

Thomas Edward Presley, Clovis, N. M.; Memphis (Tenn.) Hospital Medical College, 1896; at one time vice president of the New Mexico Medical Society; served during World War I; on the staff of the Clovis Memorial Hospital; died in St. Mary's Hospital, Roswell, January 6, aged 73, of carcinoma.

Raymond Brock Ramage, Jacksonville, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1914; member of the Florida Medical Association; died December 22, aged 53, of coronary thrombosis and arteriosclerosis.

Irving Whitmore Robbins, Vacaville, Calif.; Cooper Medical College, San Francisco, 1908; at one time served in the U. S. Navy; died December 19, aged 60, of myocarditis.

Carl Francis Schaub * Chicago; Loyola University School of Medicine, Chicago, 1929; associate professor and chairman of the department of ophthalmology at his alma mater; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; senior ophthalmologist, on the staff of Mercy Hospital; died in the Columbus Hospital January 7, aged 41, of coronary disease.

Edwin B. Tuteur * Los Angeles; Jefferson Medical College of Philadelphia, 1890; died December 26, aged 74, of osteomyelitis of the jaw and the shoulder.

DIED WHILE IN MILITARY SERVICE

John Neal Carnes, Gallipolis, Ohio; Ohio State University College of Medicine, Columbus, 1940; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on May 10, 1941; later promoted as a captain; flight surgeon; killed in the Central Pacific area in an airplane accident December 10, aged 29.

Clayton Calvin Egan Carson, Gassaway, W. Va.; Jefferson Medical College of Philadelphia, 1925; member of the West Virginia State Medical Association; served as vice president, secretary and treasurer of the Central West Virginia Medical Society; commissioned a captain in the medical corps, Army of the United States, on Nov. 11, 1942 and extended active duty began Nov. 25, 1942 at Fort Jackson, S. C.; recently assigned to the 274th Quartermaster Service Battalion; died at Camp Butner, N. C., in an automobile accident February 14, aged 43.

William Val Sanford * Ripley, Tenn.; Vanderbilt University School of Medicine, Nashville, 1918; formerly associate health officer of Rutherford County and a member of the central office staff of the state department of public health, where he had been director of the field technical service for many years; served during World War I; commissioned a major in the medical corps, Army of the United States on July 31, 1942; extended active duty began Aug. 15, 1942 at Station Hospital number 1, Fort Bragg, N. C.; died in the North African area December 5, aged 49, of coronary occlusion.

Correspondence

"GROWTH ACCELERATING PROTEIN"

To the Editor:—A communication published recently in these columns by J. L. Gabby (*THE JOURNAL*, Nov. 6, 1943, p. 655) raises certain points which lead to confusion in the interpretation of published data. The comments by Gabby are occasioned by the fact that an editorial in *THE JOURNAL*, May 22, 1943, page 232, in reviewing a preliminary paper by White and Sayers (*Proc. Soc. Exper. Biol. & Med.* **51**:270 [Nov.] 1942) on the rat growth accelerating effect of nitrogen furnished by pancreas protein also commented on results obtained by White and Sayers with "soy bean protein." From the published data the editorial writer drew correct conclusions regarding the nutritional inferiority of the soy bean protein studied but described this in terms of "soy bean dwarfism." This was a rather sweeping generalization, as White and Sayers fed not the whole soy bean meal but an isolated protein constituent of the soy bean.

Gabby's remarks create the erroneous impression that the statements in the editorial were also made in the published work by White and Sayers. On the contrary, we did not refer at all to our data with the soy bean protein, since the chief object of our investigation was to report the striking results obtained with pancreas protein nitrogen. Moreover, the preliminary results with the soy bean protein were obtained with only four animals, although since publication this number has been doubled, with confirmation of the published findings.

The protein used by White and Sayers was prepared in the classic manner often employed to prepare glycinin, one of the alkali soluble proteins of the soy bean. This protein has long been known to be nutritionally inadequate and is not, as Gabby claims, a "newcomer in the field of protein nutrition." The growth data are for the particular preparation described by White and Sayers and not for soy bean flour or for any of the other proteins of the soy bean. This does not preclude the possibility that the nutritional deficiencies in one of the proteins of the soy bean may be met by other proteins in soy flour.

Gabby also objects to the heat treatment to which the soy bean protein had been subjected. He states that he has evidence from the literature that heat in an electric oven has no appreciable effect on the nutritive quality of soy bean protein, and therefore the heat treatment used by White and Sayers did not tend to increase its nutritive value. This point by Gabby is irrelevant to his discussion, since it is clear that heat does not decrease the nutritive value. The data of Wilgers, Norris and Hensler (*Indust. & Engin. Chem.* **28**:586 [May] 1936), clearly showing the higher nutritive value of "toasted" as compared to unheated soy bean protein, are ignored by Gabby. These authors obtained their material from Hayward, who used similar soy bean products in work reported in a publication by Hayward, Steenbock and Bohstedt (*J. Nutrition* **11**:219 [March] 1936). Gabby prefers to refer to a single table in the thorough study by Hayward, Steenbock and Bohstedt. This table presents evidence that heat in an electric oven had no appreciable effect on the nutritive value of soy bean protein. It should be noted that heat is not claimed to decrease the nutritive value. Gabby does not mention other conclusions of Hayward, Steenbock and Bohstedt on pages 231, 232 and 233 of their article, which also bear on Gabby's claim that "the literature of science has many references to the high nutritive value of soy protein."

To quote from Hayward, Steenbock and Bohstedt: "Raw soy beans were found to contain protein of low nutritive value as determined by the grams of growth per gram of protein eaten . . . commercial soy bean oil meals which had been prepared at medium and high temperatures . . . contained proteins

which had about twice the nutritive value of the raw soy beans or low temperature meals. . . . The food intake of all rats which received either the raw or heated soy bean diets ad libitum was found to be similar for the first few days of the feeding period. This suggested that the poor growth resulting from the raw soy beans and low temperature meals was due to some deficiency in these constituents rather than to a lack of palatability. When casein was incorporated in the diet which contained raw soy beans, normal growth resulted. These results suggested that the deficiency in the soy bean existed in the protein fraction."

It may be added that other work on the nutritive value of soy bean protein and the nature of the difference between raw and heated soy bean protein has been thoroughly examined and reviewed by Hayward and Hafner (*Poultry Science* **20**:139 [March] 1941). These investigators have established the nutritional inferiority of raw soy beans and the increase in the nutritional value which is produced by heat treatment. Almquist, Mecchi, Kratzer and Grau (*J. Nutrition* **24**:385 [Oct.] 1942) have recently presented further evidence that raw soy bean protein, used as the sole source of protein for chick diets, has a growth limiting deficiency in methionine. Also recent analyses by Block and Bolling (*Arch. Biochem.* **3**:217 [Dec.] 1943) show that defatted soy bean meal contains less leucine, an essential amino acid, per gram of nitrogen than any one of thirteen animal and eight plant sources of protein which were examined, with the exception of gelatin.

Gabby presents growth data obtained in his laboratory claiming to show that an edible product, soy flour, is almost the same in nutritive value as the protein of spray dried skimmed milk powder. A comparison is reported between casein and soy flour, with the protein level of the diets given as 20 per cent. While the two groups of animals grew equally well, the growth rate of control animals on the casein diet is surprisingly poor. Moreover, it is possible that a supplementary protein effect to the soy flour was obtained from the yeast used by Gabby as a source of the vitamin B complex. The nutritive improvement of soy bean protein by other proteins is well known and has been pointed out in the work of Hayward, Steenbock and Bohstedt.

Soy flour may be nutritionally adequate, since it contains a mixture of proteins. It is also apparent that the nutritional value may be further enhanced by other sources of protein supplements. However, data on soy flour have no relationship to the data of White and Sayers, who fed a protein isolated from a soy bean product and not a naturally occurring mixture of proteins.

It is not our primary purpose in this communication to engage in a controversy regarding the nutritive value of soy bean products or soy bean proteins. This can be established by the published results of capable investigators. It is our desire to point out incorrect statements made by Gabby, leading to erroneous conclusions and unwarranted impressions regarding the validity of our experimental observations. The sole object of the publication by White and Sayers was to report the striking growth rate observed in rats on a diet containing pancreas nitrogen. No conclusions were drawn regarding the nutritional qualities of the soy bean protein used, and no statements were made concerning the dietary value of soy bean products. This discussion, in which it has been necessary to participate, is a result of inferences which Gabby has chosen to make and for which no basis can be found in our paper.

ABRAHAM WHITE, PH.D.,

MARION A. SAYERS, M.A.

Department of Physiological Chemistry,

Yale University,

New Haven, Conn.

MEDICAL REPORTS FOR CHILDREN SENT TO ARIZONA

To the Editor:—Will you please call attention to the fact that children sent to Tucson, Ariz., for their health should have medical reports sent with them. A large percentage of the children who are sent here by doctors in the Middle West and in the East come to us without any medical record or medical report from their family doctors.

Every year several hundred children come to Tucson for their health and attend school here from a few months to an entire school year. These children have, or have had, asthma, rheumatic fever, sinus infections or some respiratory disease of one kind or another. If the doctors who send these children to Tucson could send a medical report to the school it would help us immeasurably in planning their courses, guarding against possible injuries to their health and helping them toward complete recovery.

We often find boys and girls taking an active part in physical education programs when they should not be allowed to participate at all or should have restricted play, and some take on more school activities than they should carry.

It is sometimes two or three weeks before these children are examined, and even when a physical check-up has been made it is quite possible that some more or less serious disorder may have been missed.

ROBERT D. MORROW, Tucson, Ariz.

Superintendent of Schools.

POSSIBLE ENDOGENOUS-ALLERGIC MECHANISM OF HORMONAL ARTHRITIS

To the Editor:—I have read with the greatest interest the paper of Dr. Selye and others on the hormonal production of arthritis in *THE JOURNAL*, January 22, page 201. The very fact that they were able to produce a polyarthritis accompanied by Aschoff bodies in the heart, periarteritis nodosa and eosinophil granulomas by overdosage of desoxycorticosterone suggests the possibility of an allergic reaction.

Since these manifestations are called forth in response to repeated injections of a hormone, an endogenous-allergic mechanism may be operating. The concept of endogenous allergy is more fully described in my textbook on allergy.

Both the Aschoff bodies and periarteritis nodosa are considered today as expression of an allergic state (Rich, A. R.: *Bull. Johns Hopkins Hosp.* 71:123 [Sept.] 1942), as well as eosinophil granulomas.

The idea that arthritis may be an allergic reaction to hormones is not new, particularly in arthropathies that occur in the menopause. In addition, numerous reports testify that individuals have been proved to be sensitive to endocrine products, including adrenal cortex extract. Joël (C. A.: *Schweiz. med. Wchnschr.* 71:1011 [Aug. 30] 1941) was even able to produce antihormones to adrenal cortex extract to such a degree that fastness to this hormone resulted.

Klinge (*Der Rheumatismus*, Berlin, Springer, 1933) and Brunn (*Experimental Investigations in Serum Allergy with Reference to the Etiology of Rheumatic Joint Diseases*, London, Oxford, 1940) have shown that sufficiently sensitized rabbits will react not only to specific but also to nonspecific factors such as cold with allergic manifestations of the joints, as did the animals of Selye.

On the basis of these few considerations it has occurred to me that the pathologic lesions following overdosage with desoxy-

corticosterone may be the clinical expression of an allergy to the hormone of the adrenal cortex. While I am aware that the proof for this assumption is rather difficult to furnish, it might be ascertained by the following experimental tests:

1. The Schultz-Dale test on arthritic rat's uterus, desoxy-corticosterone being used as the antigen.

2. Determination of the antihormone titer in the blood of arthritic and of normal rats.

3. Determination of eosinophil leukocytes in the blood.

It might even be possible that the rat's skin is able to react to a cutaneous test with the cortical hormone.

It would be of the utmost importance not alone for theory but also for the treatment of arthritic persons if it would be possible to establish the allergic mechanism of hormonal arthritides.

ERICH URBACH, M.D., Philadelphia.

VISUAL TESTS FOR MALINGERING

To the Editor:—In a communication published in *THE JOURNAL* January 29 under the heading Visual Test for Malingering, Dr. J. A. C. Gabriels suggests that a man who claims inability to read Snellen type subtending 17½ minutes of arc from a distance of 20 feet (visual acuity 20/70) but who can read characters subtending 10 minutes of arc at 10 feet (visual acuity 10/20) must be malingering.

Any myope knows better than this. Many of us can read type subtending less than 5 minutes at a distance of 14 inches and can see letters subtending 5 minutes from a distance of 5 feet (visual acuity 5/5) yet cannot read type subtending 20 minutes from a distance of 20 feet (visual acuity less than 20/80).

Dr. Gabriels forgets that objects lying closer to the eye than the so-called far point may be brought to a sharp focus, but as one goes beyond the far point the image rapidly becomes blurred. One way of defining myopia is to say that the far point lies at a finite distance instead of at infinity as in the emmetropic eye. Hence tests of acuity made at a given distance are not comparable with tests at another distance, and the use of conversion formulas to transpose results obtained in one way to another notation is fallacious.

RODNEY R. BEARD, M.D., San Francisco.

M.D.—NOT DR.

To the Editor:—The physicians of this country, in connection with the preparation of many millions of forms required by various government activities, frequently neglect to have their degrees following their signatures and at times prefix their names with the word "Dr.," providing no other evidence that they are doctors of medicine.

This occasionally works a hardship on us bureaucrats because, in order to assure proper distribution of certain types of materials, supplies, equipment and services, we must determine that the applicant is a physician rather than a doctor of science, of divinity, philosophy, naturopathy, chiropractic, podiatry, chiropody or whatever.

It will be appreciated if *THE JOURNAL* at some time might contain an editorial relative to this situation and the need for a doctor of medicine to identify himself as such when his having that degree is a prime factor in determining his eligibility under certain policies.

MEDICOLEGAL ABSTRACTS

Malpractice: Treatment of Protruding Hemorrhoids by Injections of Phenol Solution.—The plaintiff had been "troubled" with hemorrhoids for about eighteen years and sought treatment in November 1940 from a corporation practicing medicine. She was attended by Dr. Harold Coe, who was an employee of the corporation and also was its secretary. Apparently a solution of phenol was injected about three or four times a week for four months into the mucous membrane under the hemorrhoids to retract the blood vessels in the tissues. In April 1941 the physician removed protruding hemorrhoids which had not been shrunk by the injections. Thereafter the patient called at the defendants' office at infrequent intervals for treatment until June 17, 1941, when she was discharged as cured. At that time no hemorrhoids were protruding and the patient "felt fairly good, though some soreness was still present." On Aug. 7, 1941 she experienced excruciating pains in the rectum and discovered a large swelling in that area and a protrusion therefrom of about a half or three quarters of an inch. She was taken to Coe's office, where, according to the patient, he gave her three injections "the same that [she] had before" and some tablets to take at home. The next day, Friday, her condition was much worse and she went to Coe's office and was given two more injections. Coe told her that she had an abscess and when it came to a head he would open it and "everything would be all right." He assured her that it "positively was not necessary" for her to go to a hospital. The next day, Saturday, her condition was worse. She was too ill to go to the physician's office and Gowans, another physician employee of the corporation, called on her, giving her an injection in the arm, which somewhat relieved her pain for the time being, and leaving her a small tube of salve with instructions as to its use. As he directed she sat in hot water three times that day for

periods of fifteen to twenty minutes at a time. However, she obtained no relief and the pain continued to become worse. About 5:30 or 6 o'clock that evening she lost consciousness. The next morning her condition was very bad. She was in a semiconscious condition and was screaming with pain. Gowans again called and gave her another hypodermic. He insisted that she be not taken to a hospital. After Gowans had left, the patient's husband called in Dr. Mastin, who found a gangrenous hemorrhoid about the size of a thumb extending from the rectum and had her removed immediately to a hospital. He could not operate then because of her condition. He gave her injections of glucose. The semicoma condition he attributed to absorption of the toxins from the condition around the rectum. The condition in which he found the patient, this physician testified in the subsequent suit instituted against the corporation and Coe, in his opinion, could not successfully be treated by the application of salve or by having the patient sit in hot water, and the course he pursued was the only proper course of treatment. Further, this physician testified that while the injection method of treating hemorrhoids is a recognized form of treating internal hemorrhoids it is not a recognized method—in fact, it is a dangerous one—for treating protruding hemorrhoids. The next morning, Monday, Mastin excised the gangrenous hemorrhoid. The gangrenous area extended upward from the base of the hemorrhoid for 3½ inches and extended posteriorly into the region of the vagina and buttocks. There was a similar, though not so large, area on the opposite side of the rectum. The patient was discharged from the hospital about two weeks later. Subsequently she sued the defendant corporation, the president of the corporation and Dr. Coe for malpractice, claiming that the infection and gangrene that developed in her from August 7 onward was due to the negligence of the defendants. At the conclusion of the evidence the defendants asked for instructions in the nature of a demurrer to the evidence and, from a refusal of the court so to instruct the jury and from a judgment in favor of the patient, the defendants appealed to the St. Louis court of appeals, Missouri.

The contention of the defendants was, in effect, that the evidence adduced before the trial court did not support a judgment in favor of the patient, and the jury should not have been permitted to pass on the questions of fact involved. In our opinion, said the appellate court, under the facts and circumstances stated above, the patient clearly made a case for the jury. From the evidence the jury could reasonably have found that on Aug. 7, 1941 the patient was suffering from a protruding hemorrhoid and that the defendants, in treating her for this condition, used the injection method, which, according to Dr. Mastin, was not a proper method for protruding hemorrhoids. The jury could also have reasonably found that because of the improper method of treatment gangrene did develop and that the patient sustained an injury and suffering that she would not have experienced had the defendants administered proper treatment.

The defendants next complained that the trial court erred in permitting the patient, over their objection, to offer evidence with respect to the treatment she had received at the defendants' office from November 1940 to June 17, 1941. There is no merit to this contention, said the appellate court. It was necessary for the patient to offer this evidence to secure a complete picture of the subject matter of the litigation. The evidence contained no suggestion that the treatment received during that period was improper, and the patient made no attempt to recover damages for anything that occurred during that time. In fact, the patient herself testified that the treatment she received up to Aug. 7, 1941 was "all right" and she further testified that so far as she knew she was cured on June 17, 1941. The court specifically charged the jury that the patient did not charge the defendants with any negligence prior to Aug. 7, 1941 and that the jury should not consider matters occurring before that date except so far as they may be explanatory of matters occurring on and after Aug. 7, 1941. In view of the claim made by the patient, the character of the evidence offered and the court's instruction, we do not see how any jury of sensible men could have been misled into allowing damages for anything that occurred previous to Aug. 7, 1941. Nor, continued the court, are we impressed with another contention of the defendants that the instruction just referred to was confusing and therefore

erroneous because it gave the jury "a roving commission to determine what matters occurring after Aug 7, 1941 are to be explained by evidence relating to treatments prior to June 17, 1941." It is the duty of the jury to sift and evaluate the evidence. The jury must be deemed to have intelligence enough to determine the logical bearing that any bit of evidence may have on the main issues of fact, without having the court specifically point it out to them. The instruction merely directed the jury to disregard any evidence with respect to the prior treatment that, to their minds, had no logical relevancy to the point at issue. Usually, this is a simple mental process, and one that the ordinary lay mind is quite capable of performing. In our opinion, the instruction was proper.

For the reasons stated, the judgment in favor of the patient was affirmed—*Shipper v Dr C M Coc, Inc, 174 S W (2d) 887 (Mo, 1943)*

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Seventeenth Annual Meeting, Held in Chicago Nov 5 1943

The President, DR JOHN WALKER MOORE,
Louisville, Ky., in the Chair

The Effect of Choline in the Transport of Fat

DR CLIFFORD H PETERS, AARON B KENDRICK, PH D, DR ROBERT W KEETON and DR JEROME T PAUL, Chicago
Choline in the doses given protects the guinea pig against deposition of neutral fat in the liver. The total cholesterol and cholesterol esters are somewhat increased, but phospholipids remain normal. The plasma of animals on experimental diets (no choline) showed definite increases in total lipids, phospholipids and neutral fats. The increases in total cholesterol and cholesterol esters were slight. The plasma of animals on experimental diets plus choline showed similar definite increases in total lipids and neutral fats. The increase in total cholesterol and cholesterol esters was more significant. There was a decrease in phospholipids with an approach to normal values. In the group of animals receiving no A or D supplements, deposition of fat in the liver was less and the cholesterol values were not elevated. In their plasma the neutral fat and phospho-

lipids fractions were elevated, but the cholesterol values were unchanged. These animals gained less weight and had a smaller traffic in fat.

These experiments support the view of fat transport that is gradually crystallizing. The choline furnishes labile methyl groups for the synthesis of phospholipids from fatty acids. When this mechanism is inadequate, cholesterol and cholesterol esters tend to accumulate. In the blood the phospholipids transporting the fatty acids accumulate until extra supplies of choline are furnished and lead to an unloading of the fatty acids in the tissues. The role of cholesterol in the transport of fatty acids seems definite, but secondary to that of phospholipids.

DISCUSSION

DR CECIL STRIKER, Cincinnati: Has Dr Keeton made studies with lipocair?

DR KEETON: Lipocair studies were reported in the second paper, in which we noted that 20 mg of choline did not protect the animals. We found no protection from lipocair. The standardization of lipocair solution is difficult and we do not feel that these experiments were conclusive.

Endogenous Hypovitaminemia A and Hypervitaminemia A

DRS HANS POPPER and FREDERICK STEIGMANN, Chicago
To study the endogenous changes which apparently are not dependent on nutritional variations, the plasma vitamin A level was determined daily or at short intervals in patients throughout the entire course of the mentioned diseases and compared with liver function tests and the response of the plasma vitamin A level to the intake of high doses of vitamin A (tolerance curve). Furthermore, the attempt was made to correct the hypovitaminemia by oral administration of vitamin A. A permanent success was obtained only with unusually large doses.

Characteristic plasma vitamin curves were obtained. In chronic liver disease, as in cirrhosis, repeated alterations between hypervitaminotic and hypovitaminotic and even avitaminotic stages were observed.

The following factors are apparently responsible for the endogenous change of the plasma vitamin A level: 1 Variation in intestinal absorption, since the tolerance curve is usually low in the hypovitaminemic and high in the hypervitaminemic stage. 2 Shift of the vitamin A within the liver from normal sites to pathologic ones, from which it is not released during the hypovitaminemic stage and from which there is an increased release in the hypervitaminemic stage. 3 Variations of factors within the plasma, such as its ability to hold vitamin A, as evidenced from the hypervitaminemia in some renal conditions in which the liver depots are low.

Cardiospasm and the Normal Esophagus: A Roentgenologic Study of Muscular Action

DRS FREDERIC E TEMPLETON and PAUL M MOORE, Cleveland
In cardiospasm the muscular action of the esophagus differs from the normal. The action is not a true peristalsis, as believed by some authors, but resembles the localized or tertiary contractions often seen in older patients.

Twenty-nine patients with cardiospasm were examined in the prone or supine positions with the "spot" machine, which eliminated the effect of gravity on deglutition. Normal as well as abnormal persons having strictures of fibrous or neoplastic origin in the lower esophagus were also observed.

In the normal esophagus three types of muscular action were encountered. The primary wave, a part of deglutition began in the pharynx and traveled down the esophagus, forcing the bolus along. The secondary wave, which was not initiated by the act of swallowing, usually began in the region of the aortic arch and progressed along the lower half of the esophagus in a manner similar to the primary wave. The tertiary or localized contraction was not peristaltic in character. The lower half of the esophagus, when distended with barium, underwent simultaneous contraction, which varied in degree, was seldom associated with symptoms, was usually momentary, was more or less segmental and did not progress along the esophagus. These changes often appeared as the primary wave reached the arch of the aorta, did not occur with every act of deglutition and were frequently seen in patients past middle age. In 3 pathologic specimens examined, only total thickening of the muscle was encountered.

In cardiospasm the primary wave, instead of proceeding to the stomach, faded out at the suprasternal notch. In the lower esophagus were peculiar, purposeless, shallow, segmental contractions which constantly appeared and reappeared at different levels. Some progressed for a few centimeters up and down the esophagus, producing an undulating appearance, but they were not sufficiently deep to move the bolus along. They were often accompanied by generalized tonic contractions, which diffusely narrowed the esophageal lumen. This tonic contraction often forced the barium mixture into the stomach, as the cricopharyngeus guarding the upper end of the esophagus remained tightly closed. Amyl nitrite caused all muscular activity to cease, the esophageal lumen to enlarge and the margins to become smooth.

In patients with obstructing lesions produced by peptic ulcer, scars from inflammation and carcinoma, the primary wave was seen.

DISCUSSION

DR. WALTER L. PALMER, Chicago: If I understand Dr. Templeton correctly, he does not include the cases of nonsphincteric spasm with those of cardiospasm. There may be some relationship we do not understand between these conditions. I wonder if Dr. Templeton's failure to note primary peristaltic waves was because the esophagus was dilated. He did observe primary peristaltic waves in certain cases of dilatation secondary to stricture, but dilatation of this type is rarely as great as that in cardiospasm. These findings are of course in accord with the view that cardiospasm is a condition resulting from some type of disturbance in the ganglion cells of the cardia and lower esophagus.

DR. TEMPLETON: Further evidence for absence of the primary wave is an esophagus filled with barium, given with the patient prone or supine, several minutes after swallowing. In the absence of obstruction, the primary wave forces most of the barium bolus into the stomach. The esophageal lumen then appears as a narrow channel.

Postvaccinal (Yellow Fever) Hepatitis; Convalescent Stage

COL. JULIEN E. BENJAMIN, M. C., A. U. S., Fort Devens, Mass.: A study of 200 soldiers who had had jaundice due to postvaccinal hepatitis returned from overseas because of inability to carry on disclosed that some had a clinical syndrome characterized by pronounced tremor of the hands and feet and extremely cold, dripping extremities, and signs of other serious vasomotor disturbances. A number of them showed evidence of hepatocellular dysfunction six months to a year after their attack of hepatitis. It has been determined in conjunction with workers at the Fatigue Laboratory that the exhaustion is actual and subject to calibration.

Preliminary Clinical Observations on the Antianemia Vitamin B₁₂ (Yeast Concentrate)

DR. E. A. SHARP, DR. E. C. VONDER HEIDE and J. G. WOLTER, B.S., Detroit: In a preliminary attempt to assess the hemopoietic activity of vitamin B₁₂ in man, 10 patients were selected. All had been under observation for a year or more and were known to be refractory to the types of therapy applied during that period. For three weeks prior to this study 21 complete blood counts were made on the group. All counts were within the range of 3.0 to 3.5 million erythrocytes per cubic millimeter and 9 to 10 Gm. of hemoglobin per hundred cubic centimeters. In addition, capillary fragility, erythrocytic fragility, prothrombin, bleeding and coagulation times, carbon dioxide combining power, total plasma protein and the albumin: globulin ratio were determined. No alteration was prescribed in diet or in mode of life. All other treatment was discontinued.

The yeast concentrate was specially prepared and assayed for this study. Calculated on the basis of the bioassay in chicks, about 1,000 micrograms of vitamin B₁₂ daily was assumed to be an effective oral dose for an adult. Since tolerance had not been determined, 600 micrograms was given daily per patient during the first week's treatment and gradually increased until all were taking 1,500 micrograms daily.

Analysis of hemopoietic data at the end of four weeks' treatment showed an appreciable increase in the hematocrit but only

slight changes in other erythropoietic phenomena. A significant increase in the globulin fraction of the plasma protein was detected at the end of the second week and continued throughout the four weeks of observation. Determinations of urine excretion of the B₁₂ factor were made on 6 of the 10 patients, which showed that the lowest excretion values were coincident with the highest plasma globulin concentration.

DISCUSSION

DR. WALTER L. PALMER, Chicago: This paper implies that there is a group of anemias which are iron resistant, which are not pernicious anemia and which are not sprue or any of the well recognized vitamin deficiency diseases. Have carefully controlled studies been made on such patients over long periods of time as to the effect of large amounts of crude yeast in the absence of iron? Do we have conclusive proof that there is a small group of anemias which are benefited by vitamins and do not belong to the specific group such as pellagra and sprue?

DR. SHARP: We encounter nonresponsive anemias not infrequently and have tried practically everything that has been offered for antianemic therapy, including large amounts of yeast, all the vitamins, iron and various combinations of liver, stomach and hormones. The patients to whom we referred have all been through that regimen in treatment in the hope a therapeutic lead of value would be encountered.

The Constitution of Prothrombin and Its Clinical Significance

DR. ARMAND J. QUICK, Milwaukee: Experimental evidence indicates that prothrombin is composed of two components (designated A and B), which are combined through calcium. When blood is stored, a progressive fall in prothrombin occurs, and likewise when an animal is fed dicumarol a decrease in prothrombin is observed. On mixing the two types of plasma, a complete restoration of prothrombin results as determined by Quick's method. The loss of prothrombin in the two plasmas therefore cannot be identical. Apparently, one essential prothrombin factor is lost in storage and another by the action of dicumarol.

For convenience the factor that disappears in stored blood has been named component A. Significantly, undecalcified blood or plasma shows no loss of prothrombin on aging. This suggests that component A when combined in the prothrombin complex is stable. The component is not adsorbed by aluminum hydroxide.

Component B is the factor which becomes depleted after feeding dicumarol and probably also in vitamin K deficiency. It appears on the body of the prothrombin complex. It is adsorbed by aluminum hydroxide from decalcified plasma but not from unaltered blood or plasma. Presumably when component B is combined in the prothrombin molecule with A and calcium it is not adsorbable.

Calcium is an essential part of the prothrombin molecule. Less sodium citrate is required to make human blood incoagulable in the presence of excess thromboplastin than that of the dog or rabbit. This is in accord with my finding that the latter contains much less prothrombin than rabbit or dog bloods. By removing the calcium the prothrombin molecule is disrupted and components A and B are liberated, but on recalcification the prothrombin complex is promptly resynthesized.

On the basis of this new concept concerning the constitution of prothrombin, a more exact classification of the various types of hypoprothrombinemias is possible. Clinically or experimentally no cases of component A depletion have as yet been found. In chloroform hepatitis a reduction of both components occurs. As a result of the present finding the pitfall in the determination of prothrombin becomes more evident. Possible errors due to the effect of high dilution on the individual components may perhaps explain discrepancies between the one and two stage methods. The use of stored blood to treat the hypoprothrombinemia due to dicumarol in the light of the new information seems logical. Since banked plasma loses only component A but retains all of its B factor, it should be as effective as fresh blood in counteracting the prothrombinopenia of dicumarol, which is characterized by a depletion of B but no loss of A.

DISCUSSION

DR. E. A. SHARP, Detroit: My experience two years ago in studying vitamin K and substitutes supports in a measure Dr. Quick's observations. I was working with whole blood, using heparin as an anticoagulant continuously in transporting blood from various institutions. During the hot weather the blood occasionally remained in the containers for several hours before being stored in the refrigerator. Two years ago I was not able to detect any difference when I determined the prothrombin immediately after storage when heparinized. However, I did find difficulties when oxalate and other anticoagulants were used.

DR. OVID O. MEYER, Madison, Wis.: The hypoprothrombinemia of vitamin K deficiency is corrected with the administration of vitamin K, as is the hypoprothrombinemia or obstructive jaundice. Large doses of vitamin K, 10 mg. administered daily, does not correct the hypoprothrombinemia of dicumarol administration, but recent work indicates that extremely large doses of vitamin K or the administration of vitamin K₁ oxide do result in correction of the hypoprothrombinemia of dicumarol administration. These observations, in view of Dr. Quick's statements, require an explanation.

DR. CARL V. MOORE, St. Louis: In vitamin K deficiencies, what changes occur in the B component of prothrombin?

DR. QUICK: In regard to Dr. Moore's question, I have had occasion to examine the blood of patients with mild hypoprothrombinemia. Cases with severe depletion of prothrombin are hard to find because they are usually treated with vitamin K early. In the cases I have studied, there has been a diminution of the component B. With regard to chloroform poisoning there is indication that both component A and component B are somewhat decreased, probably B more than A. Component A apparently is not a part of the final thrombin molecule, because in aged serum component A is still present.

Hematologic Complications of Therapy with Radioactive Phosphorus

DR. L. A. HEMPELMANN JR., DR. E. H. REINHARD, O. S. BIERBAUM, B.S., DR. CARL V. MOORE and DR. SHERWOOD MOORE, St. Louis: Severe degrees of leukopenia and thrombocytopenia have been observed in approximately one third of 49 patients with various types of hematologic dyscrasias who were under treatment with radioactive phosphorus. Seventeen patients also showed a decrease in erythrocytes. In a few instances these changes may have been produced by the disease itself, but in most cases they were attributable directly to the therapy.

Among the 49 patients included in this series, diagnoses were distributed as follows: chronic myelogenous leukemia 15, chronic lymphatic leukemia 10, leukosarcoma 3, monocytic leukemia 2, Hodgkin's disease 4, reticulum cell sarcoma 2, polycythemia vera 7, multiple myeloma 4 and mycosis fungoides 2. Twenty of these patients have died and 29 are still living. Except in the cases of polycythemia vera, the radioactive phosphorus was administered according to the simple fractional method described by Low-Beer, Lawrence and Stone; an effort was made to bring the blood counts to normal and to maintain them at or near normal levels.

The most characteristic changes which developed in the blood of the patients under treatment with radioactive phosphorus was (1) a fall in the leukocyte count, (2) a fall in platelets and (3) a decrease in erythrocytes. All three changes did not necessarily occur in the same individual. Thrombocytopenia of severe degree occasionally developed in patients with leukemia one or two months after the white blood cell numbers had fallen to approximately the normal level and the differential count had improved remarkably. Platelet counts below 100,000 per cubic millimeter were seen in 15 patients, and in many they were low enough to be accompanied both by purpura and by hemorrhage from mucous membranes. One subject with polycythemia vera developed an angina-like ulceration in her mouth when her leukocytes decreased to 1,000 cells per cubic millimeter. In no instance did any of these complications per se cause death of the patient, but in at least 7 patients they did cause symptoms and excited considerable anxiety.

The value of radioactive phosphorus in the treatment at least of patients with chronic myelogenous leukemia, chronic lymphatic leukemia and polycythemia vera is not deprecated. In most instances the changes produced in the leukocytes of patients with leukemia and in the red blood cells of subjects with polycythemia vera were satisfactory. Three patients whose platelet counts were low before treatment was begun showed a significant increase, and the erythrocyte levels of 7 patients with leukemia rose a million or more cells. Emphasis, however, is given to the fact that severe degrees of leukopenia and thrombocytopenia may be produced by radioactive phosphorus therapy. Frequent blood studies should be made during treatment so that these complications may be recognized before they become severe or before the damage to bone marrow becomes irreversible.

DISCUSSION

DR. EMMET B. BAY, Chicago: What is the half-life of radioactive phosphorus?

DR. DOUGLAS DEEDS, Denver: Were untoward hematologic reactions noted after single injections of radioactive phosphorus at intervals of approximately one month? In the treatment of polycythemia did the hemoglobin and erythrocyte count ever fall below normal figures?

DR. REINHARD: The half-life of radioactive phosphorus is 14.3 days. In most of our cases of polycythemia vera the leukocyte count, which was usually elevated above normal, began to fall two to three weeks after treatment with radioactive phosphorus was started, whereas the erythrocyte level as a rule began to fall six to eight weeks after the first treatment. In most cases the platelet count showed no significant change at any time. Several of our patients with polycythemia vera were overtreated and developed some degree of anemia. They were overtreated in spite of the fact that, as a rule, we used smaller doses of radioactive phosphorus than have been advocated by most investigators who have used this material. We believe that smaller doses than have generally been employed in the past will suffice. For the last six months instead of giving polycythemic patients a single large dose we have given them small doses at weekly intervals until the red count begins to fall; treatment is then discontinued until the erythrocyte and hemoglobin levels become stabilized. A longer time is required to get the patients under control, but there is less danger of overshooting the mark and producing an anemia.

Effect of Splenic Irradiation on Increased Vascular Erythropermeability in Purpura

DRS. F. W. MADISON, T. L. SQUIRE and S. A. MORTON, Milwaukee: Sixteen cases of purpura, entirely unselected as for etiology or presence or absence of coexisting coagulation defects, were given splenic irradiation in doses of 50 to 200 roentgens with voltage of 140 peak kilovolts and filter 0.25 mm. of copper every second or third day for three to five doses. Vascular erythropermeability was checked by the positive pressure method. Bleeding time was determined by the use of a sharp spring lancet set to penetrate 3 mm. in the ear lobe. Platelets were counted by the citrate method. All the cases were kept under observation for a considerable period of time before and after irradiation and the vascular changes checked frequently.

Thirteen cases showed moderate to pronounced reversal of the vascular lesions while 3 cases showed minimal to no response. Platelet changes were variable and transient. Alterations in bleeding time were roughly parallel to the changes in vascular erythropermeability. All the cases which failed to show vascular response were cases in which the purpura was secondary to a blood dyscrasia of leukemic type and all have terminated fatally. All the cases which showed reversal of erythropermeability were of essentially benign and reversible type, many of them being of allergic origin, and none of them have terminated fatally.

The reversal of vascular erythropermeability in the cases in which it occurred was similar to that seen after splenectomy but except in those instances in which the fundamental etiologic factors were removed was of relatively short duration, rarely lasting more than two or three months.

These findings suggest that irradiation of the spleen may be a valuable temporary measure in stopping spontaneous vascular leakage in selected cases of purpura whether or not there is an associated thrombocytopenia or hypoprothrombinemia. If such

an association exists it is extremely important to eliminate such vascular leakage promptly. Failure of response of vascular changes to splenic irradiation strongly suggests that the purpura is secondary to progressive or malignant disease. Satisfactory response to irradiation may suggest that, if other therapy fails, splenectomy is likely to be beneficial.

DISCUSSION

DR. ARMAND J. QUICK, Milwaukee: Did these spleens that were irradiated and then removed show any characteristic pathologic changes?

DR. MADISON: We have had only 1 such instance and in that case the spleen was not removed in Milwaukee, so that we did not have an opportunity to study the pathologic state of the spleen.

Effect of Digitalis on the Clotting Mechanism

DR. N. C. GILBERT, R. A. TRUMP, B.S., and DR. GEZA DE TAKATS, Chicago: The clotting mechanism of dogs was studied daily for ten to fourteen days by determining their response to heparin. After checking the normal response, we digitalized the dog to the point of intoxication. The resistance of dogs to heparin became pronounced. When digitalis was stopped, the reaction to heparin became normal. Sodium tetrathionate protected the same dogs from this heparin resistance when they were digitalized again.

Embotic phenomena have occurred after maintenance doses of digitalis have been unnecessarily raised. Our animal experiments suggest that the tendency to thrombosis is increased by digitalis; in auricular fibrillation stasis in the auricle is already present. In 6 cases digitalization, embolic phenomena and changes in the clotting mechanism seemed to coincide.

DISCUSSION

DR. EDWARD MASSIE, St. Louis: The clotting time of 24 patients was determined during an initial control period, then during digitalis administration and subsequently after the drug was stopped. The Lee-White method was used for the clotting determinations. The coagulability of the blood was found to be accelerated during digitalization in each of the 24 cases, with an average decrease of 3.3 minutes for the entire group. Statistically the results were found to be significant. In 13 cases a study was made of the differences between the clotting times during and after digitalis administration. In the majority of the patients an increase in the clotting time resulted following cessation of the medication. Studies on clot retraction and prothrombin time revealed that digitalis had no significant effect on these determinations. The mechanism by which digitalis administration accelerates blood coagulation has not been elucidated, but it is our impression that the digitaloid drugs may have a thromboplastic effect on the clotting mechanism.

DR. OVID O. MEYER, Madison, Wis.: Dr. Mead Burke in our department of pathology found that thrombosis which was frequently overlooked prior to postmortem examination was of more common occurrence in the medical than in the surgical service. He found the incidence of thrombosis to be particularly high in patients with cardiac decompensation; the occurrence was most frequent during the first week after the patient was put to bed. This we have attempted to explain largely on the basis of stasis. The period of greatest incidence corresponds to the period when the reduction of coagulation time is more pronounced following the exhibition of digitalis. The coagulation times obtained by Dr. Massie, which averaged about 13 to 14 minutes, appear to have been done at room temperatures on venous blood because they are so long. If the coagulation time is done with a water bath at a temperature of 37.5 C. the normal coagulation time is shorter, the fluctuations are less and the accuracy is greater. An average variation of between 1 and 2 minutes would be thought to be insignificant, particularly when starting with a control level of 13 to 14 minutes. Hence one should perhaps be cautious in attributing significance to these figures.

DR. L. N. KATZ, Chicago: The trend toward accelerated clotting is clear, and the evidence is therefore convincing to me. The importance of this study is that the general belief that digitalis below toxic doses will cause no harm to the cardiac

patient may not be entirely true, since the evidence in this report suggests that the clotting mechanism is facilitated. Care must be used in administering digitalis in conditions in which evidence of thrombosis is present.

DR. M. J. SHAPIRO, Minneapolis: Embolic manifestations are certainly not uncommon in patients with coronary thrombosis or rheumatic heart disease who have never received digitalis.

DR. EMMET B. BAY, Chicago: Were the animals in good condition that were receiving 0.2 to 0.3 Gm. of digitalis per day over a period of time and was there any evidence of hemoconcentration?

DR. TAKATS: Some explanation is necessary as to why we used the heparin tolerance instead of a single coagulation time. As shown by Dr. Massie, the decrease in coagulation time, while statistically significant, is not so clearcut as the change in the tolerance curve. It is only for that reason that we resorted to this test, which is no more complicated because it was taken on capillary blood. Last year the question was raised whether it is permissible to draw conclusions from the capillary coagulation time. It does not seem necessary to use venous coagulation time. In a series of patients that have a 2½ to 3 minute coagulation time one can raise them to 6 minutes by the capillary method, and we have done that. We have not intended to show that digitalis was the only factor producing embolism. I have seen just as many patients who never received digitalis develop embolism. Stasis does not seem sufficient in itself to produce thrombosis. These patients have had fibrillation for years and years. There must be a second factor operating to produce thrombosis. That factor may be infection or it may be a change in the clotting mechanism, the change which we found digitalis produces. We have previously shown with the heparin tolerance tests that in the postoperative state the patient's clotting mechanism undergoes considerable change.

Correlation of Clinical Types with Renal Function in Arterial Hypertension: II. Effect of Spinal Anesthesia

DRS. IRVINE H. PAGE, R. D. TAYLOR, A. C. CORCORAN and LILLIAN MUELLER, Indianapolis: Spinal anesthesia to the nipple line was administered to 8 patients tentatively identified as "neurogenic" and 6 designated essential, and the renal effect was observed by determination of plasma diodast and inulin clearance and arterial pressure. The levels obtained during anesthesia were compared with observations made under resting conditions. No consistent change of arterial pressure or renal blood flow or resistance was noted in the essential hypertensives, a finding in agreement with the experiences of others in normotensive subjects. In the so-called neurogenic group, all showed an increase of renal resistance blood flow and all but 1 a decrease of arterial pressure; a renal resistance was consistently decreased. These findings point to a participation of neurogenic vasoconstriction in the arterial hypertension of certain patients and suggest a means of differentiating these from patients whose hypertension and vasoconstriction are humoral in origin. It is conceivable that such a procedure as this might provide an objective basis for the selection of patients for thoracolumbar sympathectomy.

DISCUSSION

DR. GEZA DE TAKATS, Chicago: It would be extremely fortunate to have a method of differentiating patients suffering from so-called neurogenic hypertension from those having essential hypertension. Has Dr. Taylor any data on patients with normal blood pressure to indicate whether they maintain their blood pressure during spinal anesthesia? Certain patients with normal blood pressure on whom I have operated under spinal anesthesia had a rapid fall in pressure, and again others maintained the blood pressure at a stable level. The question then is whether the authors are simply measuring the state of the vasomotor center and whether this may not be the only difference between essential and so-called neurogenic hypertension. In patients operated on under general anesthesia for hypertension we have noticed a group which we would like to call neurogenic because they are sensitive to carbon dioxide. As soon as there is an accumulation of carbon dioxide the pressure rises. This led to the use of 10 per cent carbon dioxide inhalations preoperatively

to select the patients for operation. This seems to be an effective and perhaps a little simpler method than to subject the patient to a high spinal anesthesia.

DR. GEORGE E. WAKERLIN, Chicago: Was there any difference in the length of the history of hypertension in the neurogenic as compared with the essential groups? I have in mind the possibility that the neurogenic type may represent an early phase of essential hypertension.

DR. A. C. CORCORAN, Indianapolis: The effects described in this presentation are those seen during the period of roughly twenty-five minutes' full anesthesia. As anesthesia recedes and blood pressure rises, renal vasoconstriction returns in those patients in whom it had been modified by the anesthesia. The cause of the renal vasodilatation in neurogenic hypertension remains speculative. In large measure it seems to lie in the normal tendency of the renal circulation to maintain itself during changes of arterial pressure. As pressure falls arterioles dilate, and as it rises they constrict; renal blood flow and glomerular filtration pressure thus tend to remain constant during wide variations of blood pressure, and the glomerular capillaries are protected from excessive pressures. We have recorded elsewhere (Corcoran, A. C., and Page, I. H.: *Am. J. Physiol.* 126:354 [June] 1939) instances of this sort. In this view the renal vasodilatation seen in the neurogenic group effects normal response to variations of blood pressure rather than specific deprivation of abnormal vasomotor influence. The major demonstration therefore may express the greater lability of the renal vasculature in so-called neurogenic hypertension.

DR. IRVINE H. PAGE, Indianapolis: The problem of whether a certain part of patients classified as essential hypertensives are of neurogenic origin is a nebulous one. Most of us have, I think, been impressed by the large factor of nervous hyperactivity in some of these patients. Indeed I have felt that essential hypertension might in some cases have its origin in some form of nervous disturbance. There appears to be a definite correlation between the occurrence of overstimulation by the nervous system and prognosis in hypertensives. A group of patients described as having the "hypertensive diencephalic syndrome" seem to have a better prognosis than the more usual hypertensive. The term "neurogenic" implies a great deal and hence deserves to be used only with great caution. It implies that the hypertension is of nervous origin and that we know how to make the diagnosis. Certainly convincing proof has not been brought that hypertension is due to an overactive nervous system. Nor have we had sufficient objective evidence to make the diagnosis. While we recognize that study of renal function done under spinal anesthesia is not a simple bedside procedure, it may ultimately make diagnosis more certain. We hope to stimulate the search for methods which will prove or disprove the concept of "neurogenic" hypertension.

DR. TAYLOR: In answer to the question of Dr. de Takats regarding the effects of spinal anesthesia on the arterial pressure in normal persons we can only state that Smith's cases demonstrated a mean fall of —17 per cent. In the few normals we have observed, all showed a fall in pressure when the anesthesia extended to the nipple line. I am certain that many "neurogenic" hypertensives do develop essential hypertension if the condition exists long enough. Some observers have seen patients with "neurogenic" hypertension who have elevated filtration fractions. We have seen this type of patient. Further, we have seen many patients with the typical clinical picture of "neurogenic" hypertension of fifteen years' duration who have shown advancing vascular disease in the ocular fundi, the heart and the kidneys. We haven't compared the renal changes resulting from high spinal anesthesia to the effects of pentobarbital. However, 2 patients anesthetized with sodium secobarbital did not show the decreased arteriolar resistance reported here.

Treatment of Experimental Renal Hypertension with Renal Extracts

DR. G. E. WAKERLIN, CLARENCE A. JOHNSON, PH.D., W. G. MOSS, M.S., and DR. M. L. GOLDBERG, Chicago: We have recently completed studies of the therapeutic effects of a more highly purified hog renin in 1 and 3 Gm. doses, partially purified heat inactivated hog renin in 3 Gm. doses, partially purified dog

renin in 3 Gm. doses and partially purified liver extract prepared after the manner of renin in 3 Gm. doses in renal hypertensive dogs. The results suggest that the therapeutic effects of hog renal extracts containing renin are not due to renin but to some other substance or substances in the extracts, as highly purified hog renin is less effective therapeutically than partially purified hog renin. There was no correlation between the reductions in blood pressure produced by highly purified hog renin (or failures thereof) and the antirenin titers of the dogs. The results confirmed the ineffectiveness of partially purified dog renin as an antihypertensive agent in experimental renal hypertension. They suggest that the antipressor substance is partially heat stable, as heat inactivated hog renin in 3 Gm. doses was moderately antihypertensive. However, none of the dogs treated with the heat inactivated extract showed antirenin. The results also suggest that the therapeutic effects are specific for kidney and not due to a foreign protein effect, since the hog liver extract was ineffective antihypertensively. Toxic manifestations, including fever, were never observed in any of the dogs.

DISCUSSION

DR. IRVINE H. PAGE, Indianapolis: These results add to the present belief that extracts of kidneys can lower blood pressure. Renin itself does not appear to be the agent causing lowering of arterial pressure, and I think Dr. Wakerlin has given up the belief that antirenin causes the lowering of pressure, though Goldblatt is by no means ready to give it up.

DR. CARL C. SMITH, Cincinnati: A kidney extract that we use in Cincinnati was produced as the result of a long series of experiments on rats and dogs and was used for patients. It contains no renin, angiotoninase, amylase, lipase or proteolytic activity. It did reduce the blood pressure of hypertensive rats, dogs and human subjects. This would seem to confirm the suggestion of other investigators that the ability of kidney extracts to lower high arterial blood pressures may be nonspecific and does not depend on their renin or angiotoninase activity.

The Precordial and Esophageal Electrocardiogram in the Wolf-Parkinson-White Syndrome (Anoma- lous Atrioventricular Excitation)

DRS. FRANCIS F. ROSENBAUM, FRANK N. WILSON and FRANKLIN D. JOHNSTON, Ann Arbor, Mich.: We have employed thoracic and esophageal leads in the study of 8 patients with anomalous atrioventricular excitation. Seven precordial leads were taken in all cases. Additional leads from the entire circumference of the chest at the level of the cardiac apex were used in 4 cases and multiple esophageal leads in 3 cases. Transitions from anomalous to normal complexes were observed in 2 patients. Atrioventricular rhythm was produced in 1 patient. Four of the patients had had paroxysmal tachycardia. These observations suggest that in the majority of cases of anomalous atrioventricular excitation ventricular activation begins on the posterior wall near the base and toward the right margin. The variation in form of the deflections suggests that there are corresponding variations in the order of ventricular activation, but some may depend on the position of the heart. The precordial electrocardiogram in anomalous atrioventricular excitation is not characteristic of either right or left bundle branch block. These studies offer some evidence to support the accessory conducting pathway theory of anomalous atrioventricular excitation. There is no definite correlation between the standard leads and the thoracic and esophageal leads in the cases studied thus far.

DR. HANS H. HECHT, Eloise, Mich.: The syndrome which Dr. Rosenbaum calls anomalous atrioventricular excitation is rare. I have had 2 cases which were studied with serial precordial and serial esophageal leads. Both showed, as expected, premature activation of the right ventricle. Any study of this type must employ a neutral electrode. R waves in chest leads are easily influenced by a non-neutral electrode placed, for instance, on the left leg or right arm.

DR. ROSENBAUM: We have seen electrocardiograms with short PR intervals and normal QRS complexes in patients with hypertensive heart disease. In our experience the precordial electrocardiograms of such patients have shown left ventricular hypertrophy.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Treatment of Wounds by Infrequent Occlusive Dressings.—Gurd and his associates show how surgical principles can be coordinated by organized timed technic. The principles include efficient first aid by occlusive dressings, relief of pain, hemostasis and temporary splinting; excision or débridement of fresh wounds; (a) surgical antisepsis or its more recent descendant bacteriostasis; (b) surgical asepsis; wound (curtain) drainage by the employment of packing gauze impregnated with liquid petrolatum; closed or occlusive dressings; rest of the part; infrequent change of dressings with proper drainage. Closed infrequent dressings secure rest, prevent or limit bacterial contamination and improve the circulation while retaining within the dressing antibacterial and other beneficent products of the body's immunologic armamentarium in the exuded serum and chaining the wound by petrolatum impregnated gauze packing and promoting bacteriostasis. Six essential features are necessary for the success of this technic. Timing is of first importance. It is a mistake to attempt a surgical operation in fresh trauma before shock and hemorrhage are controlled. If operation is delayed too long, the risk of infection is enhanced. The second feature is efficient first aid in emergency cases by control

of hemorrhage, prevention of contamination by large sterile gauze dressings, minimization of shock by alleviation of pain, and splinting where necessary. The third feature is the control of shock and hemorrhage as far as it is possible before definitive surgical treatment is begun. This rule does not preclude the necessity for minimal early procedures to save life. The fourth factor is adequate surgery, which in fresh trauma includes exploration and wound excision and, in infection, adequate wound drainage. The fifth feature is immobilization of the part by plaster of paris, starch bandages or pressure dressings. The sixth factor is the timing of the change of dressing, which should be as infrequent as possible. The indication for changing the dressing and investigating the wound are persistence of pain, persistence of edema, persistence or development of fever and development of circulation difficulty.

Adrenal Cortex Extract in Burn Shock.—Rhoads and his collaborators report 53 cases seen at seven Philadelphia Hospitals between September 1942 and January 1943. The cases selected fulfilled four criteria: (1) at least 8 per cent of body surface burned; (2) at least an 8 point rise in the hematocrit; (3) local treatment by a tanning method except for the hands and face and genitalia; (4) plasma transfusion between the twelfth and the thirtieth hour after the burn amounting to at least two thirds of the estimated plasma deficit. They found that 12 patients with extensive superficial burns who received adrenal cortex extract did not retain plasma given by transfusion any better than did 13 control patients who received no extract.

Sulfaguandine in Bacillary Dysentery.—Page reports 520 cases of acute bacillary dysentery treated with sulfaguandine at the 151st Station Hospital in Northwest Africa. All presented typical symptoms of acute dysentery, with the passage of from five to fifty daily stools containing blood, pus and mucus and exhibited extreme prostration, chills, fever, nausea, vomiting, weakness, tenesmus, anorexia and dehydration. The patients were placed at strict bed rest in special isolated wards. The diet consisted of liquids such as bouillon, soups with added salt, tea, fruit juices, chocolate milk, liquid gruel and gelatins. The patients were usually able to retain a soft diet within the first twenty-four to forty-eight hours. A regular diet was given when their temperatures became normal. A ten day course of sulfaguandine was started immediately after a stool was obtained for culture. An initial dose of 7 Gm. was followed by 3.5 Gm. every four hours for the first forty-eight hours. After that 3.5 Gm. was given every eight hours to complete a ten day

course averaging a total dosage of 130 Gm. A bismuth compound 1 Gm. and camphorated tincture of opium 4 cc. were given every eight hours as necessary for the relief of severe abdominal griping and tenesmus. Fourteen patients failing to respond to the initial ten day course of sulfaguanidine were given a five day course of sulfadiazine. Patients were given a total of 3,000 to 3,500 cc. of fluid daily. There were no deaths or serious complications. Three cases of drug fever responded to withdrawal of the drug. More than 91 per cent (190 cases) of the positive cases were due to *Shigella paradysenteriae*, while not quite 8 per cent (18 cases) were caused by *Shigella sonnei*. *Shigella paradysenteriae* appears intermittently in the stools of both the treated and the untreated patients. Three negative stool cultures were inadequate as proof of the noninfectivity of the patient.

Staphylococcal Enterotoxin in Bread Pudding.—DeLay describes an outbreak of characteristic staphylococcal food poisoning. Enterotoxigenic staphylococci were obtained from bread pudding served at the meal following which the outbreak occurred. About 400 men were affected following an evening meal at which 600 men were served. The bread pudding consisted of bread chopped with a hand knife, pasteurized milk, evaporated milk, dried apricots, sugar and eggs. Following its preparation the pudding was placed on a shelf beneath a steam table and held until served at the evening mess of the following day. The table had been heated for one hour periods during the morning and noon mess; other than at these periods the pudding was held at about 75 F. These cases of food poisoning demonstrate the need for adequate refrigeration facilities and the necessity of using these facilities for certain foods.

Electric Shock Therapy.—Neymann and his associates report observations on electric shock therapy at the Cook County Psychopathic Hospital. In schizophrenic patients currents of 300 to 600 milliamperes at potentials between 90 and 120 volts lasting from three tenths to five tenths of a second usually produce a convulsion. In affective disorders more electrical energy is needed. A large part of the electrical energy is dissipated by passing through the skin. Daily treatments are feasible. It is suggested that the patient be treated until thoroughly confused; then he should be rested and examined as

to his insight. A second or third series of treatments may be given a patient who has not recovered after the first or second series. Subconvulsive shocks are painful and terrifying. Convulsive electric shocks are not painful and produce a short retrograde amnesia. Treatment with subconvulsive shocks was ineffective. The pure psychic suggestion of this treatment did not have much if any effect in producing the recoveries observed. Ninety schizophrenic patients were treated by this method. Thirty-one are at present listed as recovered. Twenty-one of them have been working for from six to twenty months. Eleven have been listed as improved. The recovery rate was greatest in the paranoid group. Old deteriorated schizophrenic patients who have been psychotic for years are not greatly benefited by this treatment. Fifteen patients with depressive states were treated. Eleven with depressions recovered, 4 improved. Five chronic alcoholic addicts were treated without favorable results. Dementia or flattening of the personality was not observed in the recovered group after electric shock therapy.

Death During Sulfonamide Treatment.—The subject of the report by Pollak and Ziskind was a girl aged 14 with disseminated lupus erythematosus who acquired otitis media and pneumonia complicated by cerebral signs. She was treated at different times with sulfathiazole, sulfanilamide and sulfadiazine. Necropsy revealed toxic reactions but no inflammation, particularly in the liver, kidneys, adrenal glands, pancreas and nervous system. Fatty degeneration in the liver and kidneys was far in excess of the fatty degeneration commonly accompanying pneumonia. The meningitis was obviously terminal, but its occurrence is evidence that the sulfonamides failed in inhibiting the inflammatory process, which was due to the otitis. Emboli of necrotic cells were found in the brain. These cells are most probably liver cells carried to the brain by the circulation of the blood. It cannot be decided whether the untoward effects were caused by the direct toxic action of the sulfonamides or whether they were due to an idiosyncrasy, to a disturbance in the metabolism, to an acquired hypersensitivity subsequent to the preceding sulfonamide therapy or to an especial susceptibility caused by lupus. Since administration of sulfonamides to patients with lupus erythematosus or in this disease associated with arthritis and rheumatic fever has frequently turned out to be dangerous (Fisher), the greatest caution is necessary when administering sulfonamides.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Treatment of Wounds by Infrequent Occlusive Dressings.—Gurd and his associates show how surgical principles can be coordinated by organized timed technic. The principles include efficient first aid by occlusive dressings, relief of pain, hemostasis and temporary splinting; excision or débridement of fresh wounds; (a) surgical antisepsis or its more recent descendant bacteriostasis; (b) surgical asepsis; wound (curtain) drainage by the employment of packing gauze impregnated with liquid petrolatum; closed or occlusive dressings; rest of the part; infrequent change of dressings with proper damage. Closed infrequent dressings secure rest, prevent or limit bacterial contamination and improve the circulation while retaining within the dressing antibacterial and other beneficent products of the body's immunologic armamentarium in the exuded serum and draining the wound by petrolatum impregnated gauze packing and promoting bacteriostasis. Six essential features are necessary for the success of this technic. Timing is of first importance. It is a mistake to attempt a surgical operation in fresh trauma before shock and hemorrhage are controlled. If operation is delayed too long, the risk of infection is enhanced. The second feature is efficient first aid in emergency cases by control

of hemorrhage, prevention of contamination by large sterile gauze dressings, minimization of shock by alleviation of pain, and splinting where necessary. The third feature is the control of shock and hemorrhage as far as it is possible before definitive surgical treatment is begun. This rule does not preclude the necessity for minimal early procedures to save life. The fourth factor is adequate surgery, which in fresh trauma includes exploration and wound excision and, in infection, adequate wound drainage. The fifth feature is immobilization of the part by plaster of paris, starch bandages or pressure dressings. The sixth factor is the timing of the change of dressing, which should be as infrequent as possible. The indication for changing the dressing and investigating the wound are persistence of pain, persistence of edema, persistence or development of fever and development of circulation difficulty.

Adrenal Cortex Extract in Burn Shock.—Rhoads and his collaborators report 53 cases seen at seven Philadelphia Hospitals between September 1942 and January 1943. The cases selected fulfilled four criteria: (1) at least 8 per cent of body surface burned; (2) at least an 8 point rise in the hematocrit; (3) local treatment by a tanning method except for the hands and face and genitalia; (4) plasma transfusion between the twelfth and the thirtieth hour after the burn amounting to at least two thirds of the estimated plasma deficit. They found that 12 patients with extensive superficial burns who received adrenal cortex extract did not retain plasma given by transfusion any better than did 13 control patients who received no extract.

Sulfaguanidine in Bacillary Dysentery.—Page reports 520 cases of acute bacillary dysentery treated with sulfaguanidine at the 151st Station Hospital in Northwest Africa. All presented typical symptoms of acute dysentery, with the passage of from five to fifty daily stools containing blood, pus and mucus and exhibited extreme prostration, chills, fever, nausea, vomiting, weakness, tenesmus, anorexia and dehydration. The patients were placed at strict bed rest in special isolated wards. The diet consisted of liquids such as bouillon, soups with added salt, tea, fruit juices, chocolate milk, liquid gruel and gelatins. The patients were usually able to retain a soft diet within the first twenty-four to forty-eight hours. A regular diet was given when their temperatures became normal. A ten day course of sulfaguanidine was started immediately after a stool was obtained for culture. An initial dose of 7 Gm. was followed by 3.5 Gm. every four hours for the first forty-eight hours. After that 3.5 Gm. was given every eight hours to complete a ten day

Book Notices

A. M. A. Interns' Manual. Issued Under the Direction and Supervision of the Council on Medical Education and Hospitals and the Council on Pharmacy and Chemistry of the American Medical Association. [Second edition.] FabriKoid. Price, 60 cents. Pp. 217. Chicago: American Medical Association, 1943.

This volume has been prepared with the needs of the intern as a foremost consideration. It has been designed, therefore, to provide such information as will be most helpful to medical graduates in their first period of hospital training. Thus it includes valuable data in relation to laboratory procedures, common emergencies, treatment of acute poisoning, drug therapy, dietary management, physical therapeutics, internship organization, medical licensure and other special subjects.

In the first chapter the Council on Medical Education and Hospitals describes the types of internships acceptable to the American Medical Association, the training and experience that should be obtained, the mutual obligations and relationships of hospitals and interns, the recording of educational services in the biographic files of the American Medical Association, medical licensure requirements and present standards for specialty training and certification. As further aid, particularly in relation to subsequent appointments, information has been included regarding federal, state and county services, public health, teaching opportunities, research, industrial practice and other medical assignments.

The section on Drug Administration and Materia Medica will be welcomed by all who wish to prescribe in a thoughtful and scientific manner. To this end the Council on Pharmacy and Chemistry has supplied full directions regarding methods of administration, dosage, prescription writing, equivalent weights and measures, and tables of solubilities. In addition, there is an extensive list of fifty pages giving the names, uses and dosage of all items included in the thirteenth edition of *Useful Drugs*. These have been conveniently arranged in alphabetical order.

The Council on Foods and Nutrition has contributed valuable tables and data on diets and nutrition. Similarly the Council on Physical Therapy has presented a section on physical agents that will give the interns a clearer understanding of the utilization of heat therapy, massage, therapeutic exercise, radiant energy, hydrotherapy, fever therapy and the application of low frequency currents. The legal aspects of internships have been carefully interpreted by the Bureau of Legal Medicine and Legislation of the American Medical Association. Its report on the lawful scope of intern practice should be of interest not only to interns and resident physicians but also to hospital administrators and members of intern committees. The book closes with a description of the various bodies which comprise the American Medical Association so that the reader may become thoroughly familiar with the functions and services of the organization.

The present manual is of convenient size, durable and attractively bound. It may be used either independently or as a supplemental reference in connection with established hospital rules and formularies. Its usefulness will not cease with the completion of the internship, for this handbook will continue to serve as a valuable source of reference in later periods of residency training and practice.

Notes for the R. M. O. of an Infantry Unit. By C. P. Blacker, M.C., M.A., M.D. Oxford War Manuals. General Editor: Lord Horder, G.C.V.O. Cloth. Price, \$1.50. Pp. 77. New York & London: Oxford University Press, 1943.

An excellent summary of the many and varied duties of a regimental medical officer or a regimental surgeon, as he is called in our army, is contained in the book by Dr. C. P. Blacker. In the preface the author revealed that his background consisted of combat experience as an infantry officer in World War I and three years' service as a regimental medical officer in the same organization in World War II. No attempt is made to describe official procedures or duties, but a wealth of practical and pertinent information is found in all sections of the book. It is especially recommended to the young medical officer who has just completed his medical courses and is about to enter the service. The average American might find a slightly different terminology and the use of abbreviations, a

common feature of British medical military literature, a little disconcerting at first. However, Dr. Blacker attempts to overcome these difficulties by clarity of description and the addition of the full name in parenthesis after an abbreviation is first used. On the whole it is a sound and practical guide to medical officers, both British and American.

In Divided and Distinguished Worlds: Religion and Rhetoric in the Writings of Sir Thomas Browne. By Dewey Kiper Ziegler. Cloth. Price, \$2. Pp. 104. Cambridge, Mass.: Harvard University Printing Office, 1943.

This essay is a careful analysis of the "Religio Medici" of Sir Thomas Browne. It was written by its author as an essay required of undergraduate candidates for honors degrees. He has made a thorough study of the work which was the favorite of Sir William Osler, and his analysis of the rhetoric and science shows extraordinary insight. Ziegler concludes that Sir Thomas Browne strictly divided the spheres of religion and science, as, incidentally, Pasteur did many years later. Of religion Browne demanded only imaginative satisfaction. His "Religio Medici," though it fails as a philosophy, is a magnificent demonstration of the use of language for emotional, intellectual and sensuous enjoyment.

Kaiser Wakes the Doctors. By Paul De Kruijf. Cloth. Price, \$2. Pp. 158. New York: Harcourt, Brace & Company, 1943.

A favorite indoor sport among physicians today is the "panning" of Paul de Kruijf, whose enthusiasms frequently eclipse his judgment and perhaps sometimes even his powers of observation. His current enthusiasm is the system of medical care established by Henry Kaiser for the workers in his shipbuilding plants. At least two medical writers, Drs. George H. Kress in *California and Western Medicine* and Floyd T. Romberger in the *Journal of the Indiana State Medical Association* have meticulously picked this book to pieces and left it of little of virtue. Those readers who think it worth while may refer to these contributions to confirm the opinion that the book is more propaganda than qualified sociological or medical study.

The Biochemistry of Malignant Tumors. By Kurt Stern, M.D., and Robert Wilhelm, M.D., Professor, University of Philippines, Manila. Cloth. Price, \$12. Pp. 951. Brooklyn: Chemical Publishing Company, Inc.; Reference Press, 1943.

This book reviews the literature of biochemical research in the field of cancer to the end of 1941. It is an enlarged continuation of the book on the same subject published by the same authors in Vienna in 1936. The chapter captions will indicate the nature and scope of the contents: inorganic chemistry, organic chemistry, physical chemistry, enzymes, nutrition and vitamins, metabolism, endocrines, immunology, tumor origin and growth, tumor diagnosis. An enormous amount of material is reviewed. Thus the number of names in the author index is about 3,500. The work appears to have been well done. The book will facilitate a study of the literature of the biochemistry of cancer.

The Case of a A. L. —, Aged 56: Some Curious Medical Aspects of Lincoln's Death and Other Studies. By Otto Eisenschiml. Cloth. Price, \$3.50. Pp. 55, with 3 illustrations. Chicago: Abraham Lincoln Book Shop, 1943.

In a small well written booklet Dr. Eisenschiml carefully analyzes the fatal gunshot wound of President Lincoln. Every detail of the medical aspects of the assassination is reviewed, such as the exact position of President Lincoln and John Wilkes Booth at the time of the shooting, the probable path of the missile through Lincoln's brain, the medical and nursing care given to Lincoln after the shooting, and the varied postmortem reports. The addition of the last chapter entitled "If Lincoln Had Lived," though an intriguing historical speculation, detracts from an otherwise scientific treatise.

Metabolism Manual. By Jessie K. Lex, R.T., M.T., Chief Medical Technologist, the Parker Diagnostic Clinic, Peoria, Illinois. Cloth. Price, \$1.75. Pp. 56, with illustrations. Peoria: Metabolism Department, Parker Diagnostic Clinic, 1943.

This misnamed monograph actually deals with the technic and interpretation of the basal metabolism test as performed with an apparatus of the Roth-Benedict type. It is intended to instruct the technician in handling both the apparatus and the patient, and in distinguishing between a reliable and a faulty test. It is clear that the authoress is a well trained and conscientious technician. But the material is incomplete and not well presented. The style is pompous and prefix.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SYSTEMIC DISEASE AND FERTILITY

To the Editor:—In May 1943 a patient had a sudden onset of gross hematuria while apparently in good health. He is 25 years old and has no history of kidney disease. Repeated ureteral catheterization showed the hematuria to be bilateral. Kidney function was unimpaired; blood pressure stayed at its old level of 126/82; there was no anasarca or significant drop in plasma proteins. After four months, two of which were spent in bed, the hematuria cleared, but the albuminuria persists in some degree to the present. The diagnosis, arrived at after some hesitation, was acute glomerulonephritis, now in the subacute stage. The nonprotein nitrogen incidentally was never elevated, and the sedimentation rate was normal throughout. The red blood cell count dropped from 5.3 million to 4.5 million, but the white blood cell count remained the same. He never had any temperature rise. He and his wife have been trying to conceive for the last six months without success. His sperm count is about 17.5 million per cubic centimeter and the sperm seem actively motile, with good progress across the field. There are fewer than 5 per cent abnormal forms. His ejaculate contains about 2.5 cc. The Huhner test is positive for living, motile sperm after three hours. Before beginning investigation of the wife, I should like to ask whether the patient's nephritis would have any effect on his ability to conceive. Could you give me any references in the literature to the effect of systemic disease on sperm formation and conception? Is anything known about the likelihood for abnormality in the fetus in such cases?

M.D., New York.

ANSWER:—Stock breeders have long recognized the depressing effect of systemic disorders on the fertility of their flocks, droves and herds. In recent years much evidence of a similar phenomenon in human beings has accumulated. Constitutional ailments are frequently correlated with poor semen, which improves when the former are corrected (Meaker, S. R., and Vose, S. N.: *The Nature of Human Infertility*, *THE JOURNAL*, Oct. 26, 1940, p. 1426). The treatment of such conditions in either sex is followed by pregnancy often enough to make a cause and effect relationship highly probable.

In these cases the first pregnancy not uncommonly terminates in abortion. Such an event signifies that the fertility level has been raised above the threshold of conception but is not yet high enough to endow the fertilized ovum with that degree of vitality necessary for its continued growth. The result is early ovular death rather than the development of a monster. Mall states categorically that all monstrosities are due to faulty implantation and not to imperfections inherent in the ovum.

The constitutional disorders known to depress fertility include the entire group of endocrine underfunctions, most often those of the anterior pituitary and the thyroid; chronic poisonings, notably toxic absorption from foci of infection; faults of diet and hygiene, and conditions leading to general debility. It is conceivable that acute glomerulonephritis might fall into this last category, but no observations as to its effect on fertility have been recorded.

The majority of highly fertile men show sperm counts of 100 million or better. Evaluations of morphology vary according to the standards of the individual examiner, but all experienced workers agree that even the best specimens contain around 15 per cent of immature or otherwise imperfect forms.

Another specimen of semen should be examined when the patient has entirely recovered from the effects of his illness. If this is not found to be satisfactory as to numbers, morphology, motility and endurance of the spermatozoa, further study of the case will be indicated, with special reference to endocrine factors.

"SENILE WARTS" REQUIRE INVESTIGATION

To the Editor:—Many elderly persons are distressed and disfigured by "senile warts." Is there any satisfactory "wholesale" treatment for this condition. Must they be attacked and remedied individually?

Ursula G. Mandel, M.D., Los Angeles.

ANSWER:—Senile warts are not warts in the strict sense. The term is usually applied to what are either senile keratoses or seborrheic keratoses. There is a great deal of confusion in the literature about these diseases. Eller and Ryan (*Senile Keratoses and Seborrheic Keratoses*, *Arch. Dermat. & Syph.* 22:1043 [Dec.] 1930) have presented a clear differentiation between them, and the discussion that followed their paper is illuminating. Both forms are local growths not amenable, as far as is known, to any general treatment. The important point brought out by the paper cited is that, on the face especially, less often on the neck or trunk, lesions that appear clinically to

be seborrheic keratoses sometimes prove on microscopic investigation to be senile keratoses. They are therefore potentially dangerous growths masquerading as comparatively innocent ones. Efficient treatment of either form requires an investigation to determine whether epitheliomatous degeneration has begun under the surface tumor.

OPTIC MANIFESTATIONS ASSOCIATED WITH MALARIA OR CINCHONISM

To the Editor:—What is the etiology and mechanism of production of the exudative papillitis found in recurrent malaria? Is it due to the malaria, to the quinine or to the atabrine? A sufficient number of visual field changes in patients with recurrent malaria (five or more attacks), generally with varying amounts of internal antimalarial medication, have occurred to make these studies of importance. The classic retinal picture in cinchonism is, of course, contracted retinal arteries, pallid retina and contracted fields (Duke-Elder, vol. 3, p. 3032). Goodman and Gilman (*The Pharmacological Basis of Therapeutics*) concur (1940 ed., p. 910) but on page 907 (cardiovascular system) indicate that vasodilatation is part of the toxicology. What are the true cause and mechanism of the exudative vasculitis of the disk?

Major, M. C., A. U. S.

ANSWER:—It is impossible in the present state of our knowledge to give a categorical answer to these questions. It is generally accepted that, in cinchonism, the optic disk is pale and the retinal arterioles are constricted. It is not definitely known, however, whether the loss of vision is the result of primary ischemia of the retina or whether it is due to direct toxic action of quinine on the ganglion cells of the retina. The vasodilating action of quinine seems to be a selective one affecting particularly the vessels in the skin and in the extremities. Advanced degrees of vasodilatation are associated in the main only with toxic doses of the drug. No specific toxic effects have been noted with the use of atabrine in accepted dosage or even after considerably larger doses than are prescribed ordinarily. Certain psychotic manifestations have been ascribed to the staining of the brain similar to that which occurs in the skin.

It must be assumed, therefore, that the lesions noted in the optic nerve and retina and presumably the changes in the visual fields are associated with the malaria and not with the medication. The exact mechanism of the production of these lesions is not so clear, however. With *Calci-parum* infections, in cases of malignant malaria, the capillaries, including those in the retina, choroid and brain, are filled with red cells containing the plasmodia, and neighboring tissue lesions can result either from a direct toxic action or from actual thromboses of vessels. With vivax infections, however, this packing of the capillaries does not occur, apparently. Lesions developing in the retina and choroid during an acute febrile stage of vivax malaria must be assumed, then, to be the result of the general toxemia and to be similar to those found in association with other febrile diseases such as pneumonia or influenza. It must be borne in mind, however, that most patients with recurrent malaria are anemic, cachectic and undernourished. Some of the hemorrhages in the retina, the lesions of the optic nerve and the changes in the fields of vision may then be due to the associated anemia, malnutrition and avitaminosis rather than to the malaria infection itself. Further study on these points is definitely indicated.

EXOSTOSIS OF AUDITORY CANAL

To the Editor:—At the age of 47 I suddenly find that I have an exostosis of the ear canals. There is no history of any ear disease other than a mild fungus infection several years ago. When examined at that time no mention was made of an existing exostosis. Is exostosis of the ear canal a congenital disease?

Lieutenant Commander, U.S.N.R.

ANSWER:—By exostosis is meant a circumscribed bony growth of the external auditory canal as distinguished from the flatter, broader and more diffuse form which goes by the name of hyperostosis. As Politzer says, one is seldom in a position to observe clinically the growth of these exostoses, as they are not accompanied by inflammatory phenomena. Symmetrical multiple bilateral exostoses are probably hereditary in origin and are thought to be as a rule true bony tumors. Some solitary growths may resemble externally true bony tumors but are thought by many to arise in part, at least, from ossification of chondromas or hyperplastic periostitic areas caused by minor traumas and irritations.

If the original observation as mentioned was accurate and it is reasonably certain that no growth was present several years previously, then the condition present is surely not congenital but acquired. It is only fair to say that there is much about the origin and histologic structure of these growths which is obscure and indefinite. Dogmatic statements are hence undesirable.

INFLAMMATORY DISORDERS OF THE SKIN OF THE FEET

JOHN F. MADDEN, M.D.
ST. PAUL

The anatomic peculiarities of the feet, the fact that they are organs of locomotion and the fact that they are enclosed in shoes make the skin which covers them subject to certain diseases. This paper is part of a symposium on cutaneous disorders of the feet; so stress will be laid on conditions which occur on the feet alone, and little will be said about those in which the feet are involved as part of a disseminated process.

The diagnostic approach to cutaneous diseases of the feet should be made with an open mind. There is a tendency among both the public and doctors to call all diseases of the skin of the feet fungous infections. It is actually impossible to make a diagnosis of a fungous infection without microscopic studies of scrapings from the cutaneous lesions or from their contents. Often the aid of cultures is also necessary. Even if a fungus is found, it is often difficult to determine whether it is a saprophytic or a pathogenic organism. The public seems to have a preconceived idea that football coaches, athletic trainers and the like are capable of diagnosing and treating fungous infections, or "athlete's foot." This idea is readily accepted by the coaching fraternity. Some of the athletic instructors have even gone so far as to endorse certain compounds as cures for any and all inflammations of the feet. My associates and I seldom see high school students or college men who participate in athletics and have cutaneous disorders of the feet who have not been treated for various lengths of time by their coaches. Fewer diagnostic errors would be made if fungous infections were diagnosed as a last resort.

The examination of the feet is most important. It is absolutely necessary to examine both feet. The patient is often reluctant to take the covering off both feet, but this should be insisted on. The hands should also be examined, and if an eruption is present it is important to know whether the eruption started on the hands or on the feet. The skin should be examined at least up to the knee as well as the part covered by the eruption. All parts of the feet should be examined. The circulation, the shape of the feet and physical abnormalities should be noted. The webs of the toes, the nails and the paronychia tissues are to be carefully considered.

It is equally important to examine the footwear. Woolen socks are generally contraindicated in inflam-

matory conditions of the feet. They absorb and hold moisture and produce maceration of the inflamed skin. Cotton footwear is much less irritating. Shoes are to be examined for type and comfort as well as fit. Generally a comfortable shoe is a well fitted shoe. Perforated shoes and open toed shoes are far superior to the usual footwear when inflammation exists. They probably are preferable at all times, but certain occupations as well as the winter season make their general use impracticable. Thick soled shoes as well as rubber soled shoes are undesirable in the presence of inflammation because they increase perspiration and cause maceration. Thick soled or rubber soled shoes also cause inflammatory conditions by producing increased perspiration which results in maceration, and this in turn is followed by inflammation produced by the common saprophytic organisms on the feet. It is important to know how often the patient changes his shoes, how many shoes he has and whether he wears one pair for work and others when he is not working. Shoes should be changed frequently in the presence of inflammatory disease. Wet, soggy shoes always aggravate inflammatory conditions. The patient should have enough changes to allow the shoes to dry thoroughly before they are worn.

Certain occupations add to the hazards and often are predisposing causes of inflammatory conditions of the feet. This is especially true of butchers, workers in meat packing plants, butter makers and people who wear rubber boots or rubbers and stand in water or on a wet floor all day. When these people get inflammatory diseases of the feet it is usually necessary to have them stop work temporarily or change to another occupation. Oil soaked shoes worn in some occupations are aggravating factors in inflammations. This is especially true if the patient does not leave his work shoes at the plant but wears them walking around after work.

The general public is tempted to use all sorts of remedies because of persuasive newspaper and radio advertising. It should be obvious that a "cure all" does not exist. The type of treatment varies with the stage and the degree of each inflammation, with every case and with each recurrence in the same patient. Most of the remedies advertised are too strong for general use and add to the existing trouble. Home remedies such as tincture of iodine, gasoline and kerosene usually aggravate even the mildest inflammation. Soaking shoes in formaldehyde has caused many a sore foot and did not benefit or prevent cutaneous diseases of the feet. The most discussed and advertised use of equal parts of phenol and camphor has done a great deal of harm and has been said even to have caused gangrene in some instances. Generally foot powders are harmless even though they often are not beneficial.

The care of the feet and of footwear is important in preventing inflammations as well as in treating inflammatory disease. Shoes that rub, pinch or bind the

This paper, in a symposium on "Cutaneous Disorders of the Foot," is published under the auspices of the Section on Dermatology and Syphilology.

From the Ancker Hospital and the Division of Dermatology and Syphilology of the University of Minnesota Medical School, Dr. H. E. Nicholson, director.

feet should not be worn. Shoes with run down or worn heels which place the feet in abnormal positions are harmful. The nails should be cleaned, cut and trimmed regularly. The feet should be bathed often and dried carefully. It is especially important to dry between the toes, where many inflammations start.

Constitutional factors also play an important part in inflammatory diseases of the skin of the feet. The circulation can and often does have a determining role in the effect of local treatment. The build and the weight of the patient have a definite effect on therapy. It is well known that obese people do not respond to local treatment as well as others. Sweat is an aggravating factor in some inflammatory conditions of the skin of the feet, especially contact dermatitis and fungous infections. The salt in sweat irritates open lesions, and often the eruption cannot be controlled during periods of excessive sweating. The seasons, emotional factors such as nervous exhaustion, worry and fright, and fatigue have an uncontrollable effect on sweating of the feet and secondarily on inflammations of the skin. Chronic inflammations of the feet usually become worse after excessive sweating in the spring, after alcoholic bouts and following periods of nervous exhaustion, over which local treatment has little if any control.

The inflammatory disorders of the skin of the feet to be discussed will be taken in the approximate order of their frequency and importance.

CONTACT DERMATITIS

Contact dermatitis usually appears on the dorsa or the sides of the feet and is rarely seen on the soles. The nails and the interdigital webs are seldom involved.

The eruption may range from inflammatory weeping vesicles to diffuse dry scaling plaques. The location is quite the opposite of that of fungous infections. As in contact dermatitis elsewhere, the most prominent symptom is itching. This varies both with the patient and with the degree of inflammation. Swelling may be pronounced enough to prohibit the wearing of shoes. The usual causes of contact dermatitis are shoe dye, sock or stocking dye, leather or shoe polish. Dermatitis from poison ivy is frequently seen on the feet of bathers and children in the summer time. Leg makeup and nylon hose have caused a certain amount of contact dermatitis in recent years. Although nail polish is frequently worn, it seldom if ever causes dermatitis in this area. A careful history aided by patch tests or actually withdrawing and later wearing the suspected article will generally reveal the cause. It is important not to overtreat contact dermatitis. If the feet are swollen, wet packs of boric acid or a solution of aluminum acetate in addition to boric acid or warm water soaks two or three times a day can be used. The packs should be made of approximately twenty layers of washed surgical gauze and changed frequently. Rubber, oiled silk and other impermeable substances should not be applied on the outside of the pack because they defeat the purpose of the pack by prohibiting evaporation and causing maceration. Boric acid in a saturated solution should never be used because the boric acid crystallizes as the pack dries and the crystals mechanically irritate open lesions. After the edema has subsided, a paste consisting of 3 to 5 per cent ichthammol in paste of zinc oxide is applied. The patient is advised to wear perforated shoes for some time after the eruption has healed.

PYODERMA

When pyoderma is used in the broad sense meaning any pyogenic infection it designates a condition that is relatively common on the feet. Inflammations may start following injury from falling objects, shoe nails, stone bruises on bare feet, tight shoes, rubbing shoe heels, ingrown toe nails and many other causes. When the cause is removed, it often is not necessary to keep the patient off his feet. Warm water or boric acid soaks at intervals during the day and 5 per cent sulfathiazole ointment applied at night and between soaks usually are sufficient. For the more severe pyogenic infections rest in bed, elevation of the feet and wet packs of boric acid or of solution of aluminum acetate are applied until the patient becomes ambulant. Sulfathiazole is not given by mouth unless the infection is severe or accompanied by lymphangitis or lymphadenitis. The usual precautions against tetanus are taken when necessary.

Certain types of pyogenic infections deserve special mention. Ecthyma has been one of the most severe medical problems of the war in Africa. The British literature shows an astonishing number of articles under many different names devoted to ecthyma. It seems that the soldiers get indolent pyogenic ulcers following insect bites and other injuries which will not heal under conditions of desert warfare. The lack of bathing, the long marches and the ever present sand in the air are given as reasons why the lesions do not heal. Ecthyma as we see it in Minnesota usually responds promptly to 5 per cent sulfathiazole ointment. The addition of 3 per cent urea to sulfathiazole ointment seems to be beneficial.

Folliculitis due to oil is seen on the feet of mechanics, press workers, engineers and others who wear oil soaked shoes while working. The recurrence of such infections has become a real industrial problem because these people usually are skilled workers and cannot be shifted about. The patients are advised to change socks at least once a day, to bathe their feet twice daily, to change shoes every two or three days and to wear different shoes while working. Sulfathiazole ointment is used locally. If the eruption recurs, the usual protective creams are used.

Erysipelas, cellulitis, furunculosis and impetigo occasionally occur on the feet. The sulfonamide drugs are always administered cautiously by mouth and only when there are real indications. When sulfonamide drugs are given by mouth the urine and the blood are checked regularly and careful observations made for other toxic signs. It is rare to find a case of "sulfathiazole fast" impetigo contagiosa, although it is quite common to have sulfathiazole ointment cause contact dermatitis.

PARONYCHIA

Paronychia is usually due to pyogenic infection, fungous infection, psoriasis or syphilis. Paronychia caused by pyogenic organisms is generally secondary to ingrown toe nails. The cause is evident but the treatment is difficult. Often the outer third of the nail must be removed and the part then treated with wet packs and soaks in the manner previously stated. Pyogenic paronychia often is accompanied or followed by pyogenic granuloma which is not affected by local applications and must be destroyed by some type of cautery. Paronychia associated with psoriasis is really due to pyogenic organisms and is started by psoriatic distortion of the nail. The psoriatic nail is often benefited by superficial roentgen therapy, while the par-

onychia is treated as one of pyogenic origin. Syphilitic paronychia is not particularly distinctive but is usually accompanied by dactylitis, changes in the nail, and a positive serologic reaction.

PSORIASIS

When psoriatic lesions of the feet are part of a generalized eruption the diagnosis is simple. However, psoriasis may be confined to the soles or the nails for many years or a lifetime. The soles are dry, scaly and often fissured. There rarely is involvement of the interdigital webs as in fungous infections. The eruption is more diffuse than in the occupational keratodermas and usually starts in childhood or later life in contradistinction to the congenital keratodermas. Patients with diffuse papulosquamous syphilids generally show other signs of syphilis and have a positive serologic reaction. Squamous eczemas usually can be differentiated by biopsy. The nails are thickened, irregularly laminated, brittle and yellowish white. Psoriasis can be differentiated from fungous infections by direct and cultural examinations of scrapings. Arthropathic psoriasis is the name given to the association of polyarthritis and widespread psoriasis of which the involvement of the feet is only a part. Pustular psoriasis on the feet as elsewhere is a more acute phase of psoriasis vulgaris. Certain lesions of pustular psoriasis often subside or become typical lesions of psoriasis vulgaris; also the reverse is often seen. Psoriasis may involve the feet as part of a generalized exfoliative dermatitis and must be differentiated from exfoliations due to arsenical or other drugs, the lymphoblastomas, exfoliative seborrheic dermatitis and lichen planus. This usually can be done by means of a careful history, examination and biopsy. The cause of psoriasis is unknown, and the recent clinical investigations seem to have thrown little light on it.

The treatment of psoriasis has made little advance in many years. Innumerable remedies have been publicized in glowing reports only to be found wanting when checked by less enthusiastic investigators. I have conducted special psoriatic clinics at the Ancker Hospital and the University Hospitals for several years and have observed over 500 psoriatic patients. All the newer remedies and methods of treatment brought to my attention have been tried over long periods. Almost all remedies will help a small percentage of psoriatic patients, but no remedy will benefit all or even a sizable percentage. It is also interesting to note that in my experience most remedies will not take care of recurrences satisfactorily no matter how effective they were the first time. To my mind the Goeckerman tar and ultraviolet ray treatment for hospital patients and the usual topical applications for ambulant patients are still the most satisfactory. It is well to warn that repeated roentgen therapy to the soles is harmful and probably should never be used.

Since my last report a number of remedies have been used because of their reported successful effect on psoriasis. Soybean lecithin given in capsules and in cookies, eosin used locally in lotions and ointments, parathyroid injection subcutaneously, Honduran sarsaparilla in tablet form by mouth, and pancreatin in tablet form given by mouth were all tried over a period of months, and they did not cure psoriasis. Of the aforementioned remedies pancreatin in 5 grain (0.32 Gm.) tablets given four times daily by mouth combined with a scaling ointment seemed to be the most satisfactory.

DISTURBANCES OF THE SWEAT GLANDS

Hyperhidrosis is often accompanied by a certain amount of inflammatory change in the skin. It often paves the way for more serious conditions as well as aggravating existing inflammatory diseases. Hyperhidrosis may be caused by a disease of the thyroid gland, obesity, tuberculosis, chronic alcoholism, emotional disturbances and many other diseases. The cause should be removed when possible. Careful drying of the feet, frequent bathing, avoiding wool socks, changing shoes and socks daily, allowing shoes to dry thoroughly before wearing, avoiding thick soled or rubber soled shoes, wearing perforated shoes, using a harmless dusting powder in the footwear and applying an aqueous solution of 15 per cent aluminum chloride are helpful. Here again repeated roentgen therapy should be used cautiously.

Bromidrosis can be described as hyperhidrosis with an odor. The causes and the treatment of the two are essentially the same.

Dyshidrosis is an acute or subacute inflammatory condition occurring on the hands and the feet. The lesions occur on the soles and the interdigital webs. The eruption appears as deep seated solitary vesicles which itch intensely. The lesions later rupture and scale or they may coalesce and form clusters. The degree and the signs of inflammation vary. The eruption often becomes pustular, and it may be a forerunner of fungous infections or pyodermas. Dyshidrosis is less frequent and less severe on the feet. It has a tendency to recur repeatedly. In my experience the eruption frequently follows periods of overwork, nervous exhaustion or emotional disturbance and is often accompanied by hyperhidrosis. Treatment is directed toward correction of the general disturbance when one exists, use of the same drying measures as mentioned for hyperhidrosis and use of local applications. The use of 3 to 5 per cent salicylic acid and 3 to 5 per cent benzoic acid in paste of zinc oxide often gives satisfactory results.

LICHEN SIMPLEX CHRONICUS

Lichen simplex chronicus occurs on the dorsa of the feet and at the instep from ill fitted shoes and other causes. It is not always localized neurodermatitis. In some cases it is due to purely mechanical irritation by a foreign object on the skin and will disappear with little or no treatment when the offending object is removed. I have observed this several times when trusses were removed following operation for hernias. Lichen simplex chronicus is a circumscribed patch of chronic inflammation characterized by thickening of the skin, a dull red color, accentuation of the lines of cleavage and presence of excoriations. If the cause can be removed the disease often responds to fractional doses of roentgen rays plus a local application of 1 to 5 per cent crude coal tar in paste of zinc oxide. A recent favorite application of mine obtained indirectly from Dr. J. B. Shelmire of Dallas, Texas, is salicylic acid 0.5 Gm., mercuric salicylate 1 Gm., oil of eucalyptus 1 Gm., bismuth subnitrate 2 Gm., hydrous wool fat 15 Gm. and white petrolatum 15 Gm.

PERSISTENT ERYTHEMA OF PALMS AND SOLES

Persistent erythema of the palms and soles is much more common than is generally known. Little attention is paid to the eruption because it is often asymptomatic. It usually occurs over the points of pressure on the feet and remains for months or years. Some-

times there is an accompanying hyperhidrosis, and at times the feet itch or burn. There are constantly patients with this eruption in the wards for tuberculosis at the Ancker Hospital. I have seen as many as 10 of 150 tuberculous patients with it. The significance of the erythema was never determined but it was not seen in patients who did not have tuberculosis. Several biopsies were made and no abnormalities were noted. Fractional doses of roentgen rays, drying and scaling ointments and lotions, as well as other applications, did not affect the eruption. A recent article by Nelson¹ may be a step further in the foregoing description and might show the different findings in ambulant patients in his group and bed patients in mine. However, the uniform favorable response of Nelson's patients to treatment leads me to believe that we are not discussing the same disease.

RADIODERMATITIS

Radiodermatitis is all too common on the feet. It generally follows treatment for one of the common recurrent cutaneous eruptions, such as psoriasis and fungous infections, or treatment for plantar warts. Chronic radiodermatitis is usually found on the feet, and it appears in the form of atrophy, hyperpigmentation or depigmentation associated with telangiectasia. This is particularly dangerous on the feet because of the constant trauma and possible development of cancer. When radiodermatitis is present, the feet need especially good care and careful observation at regular intervals. The possibility of cancer should always be kept in mind when the slightest roughening of the surface or ulceration appears. Cancers in radiodermatitis in this location are usually intensely malignant and require immediate attention if cure is to be had.

URTICARIA

The feet may be the only site of urticaria. The eruptions usually occur on the soles and itch annoyingly. The eruption may be caused by any of the many recognized causes, but often there is a particular type spoken of by the French as "fatigue urticaria." At the time of emotional stress or nervous exhaustion the feet will develop urticarial lesions and itch intensely. This continues until the emotional wrong has been righted, in spite of the use of the usual helpful medicaments, such as epinephrine or ephedrine.

GRANULOMA ANNULARE

Granuloma annulare often occurs about the ankles and on the dorsa of the feet. The lesions consist of deeply seated papules which are elevated, firm, vary from the color of normal skin to bluish red and generally form a ring. There are seldom more than one or two ringed lesions on a foot. The lesions usually develop slowly and persist for months or years. They may involute partially and leave single papules or segments of the ring. They are usually comparatively painless. Opinion is divided as to whether the eruption is of tuberculous origin. The disease may be differentiated from erythema elevatum diutinum, erythema multiforme, necrobiosis lipoidica diabetorum, annular sarcoid and rheumatic nodules. Solidified carbon dioxide and radiotherapy are sometimes used satisfactorily. Occasionally a lesion will disappear following biopsy, but often any treatment is ineffective. Granuloma annulare generally involutes without sequelae.

ACRODERMATITIS PERSTANS

Acrodermatitis perstans is a comparatively rare disease of the skin of the feet. It is a chronic infectious dermatitis which usually begins in the region of the nail and spreads slowly from that point. The initial lesions are vesicular or pustular. Later the nails are thickened and may be destroyed. The pustules recur and rupture, and the involved part is covered with crusts. The hands are more commonly the site, but the disease may involve all parts of the skin and mucous membranes. Acrodermatitis perstans is confused with infectious eczematoid dermatitis and pustular psoriasis. Local antiseptic applications are used but often are of little value.

PUSTULAR BACTERID

Pustular bacterids are described by several authors, but I have never seen a case with all the classic findings, so have never made such a diagnosis. The eruption is discussed in detail by Andrews.² The following lines are direct quotations from his book: "The disease usually begins on the midportions of the soles, the characteristic lesions are pustules, the histology is distinctive and the distinguishing facts concerning pustular bacterids are (1) the presence of skin lesions that have a proved relationship to a focus of infection, sometimes accompanied by leukocytosis; (2) positive allergic skin reactions to streptococcus and staphylococcus, (3) consistently sterile cultures from skin lesions, (4) cure by removal of the focus of infection and (5) uniform histopathology similar to that of trichophytid. The treatment of pustular bacterid is chiefly the problem of eliminating all foci of infection. Locally, wet dressings of solution of aluminum acetate diluted 1:4 give the best results."

AINHUM

Ainhum is a rare disease seen chiefly among Negroes. It affects any of the digits but most frequently the little toe. A shallow groove is formed on the digitoplantar web, which spreads and encircles the digit. This constricting fibrous ring tightens and in time amputates the toe. In early stages the digit can be saved by severing the constricting ring.

INFLAMMATORY DISORDERS OF THE SKIN OF THE FEET CONSTITUTING PART OF A DISSEMINATED ERUPTION

Erythema multiforme is commonly seen on the dorsa of the feet as well as on the backs of the hands and on mucous membranes. It is a disease of multiple causes, among which are drugs and allergens. When the cause is removed the disease disappears promptly, but in the as yet idiopathic group small doses of neoarsphenamine, 0.3 Gm. given every three to five days, are often of distinct value.

Pellagra shows cutaneous as well as gastrointestinal and nervous system signs. The skin of the feet is less severely and less often involved than that of the hands, face and neck. When dermatitis occurs it appears as an erythema on the dorsa of the feet and about the ankles. This is followed by edema, hyperpigmentation and desquamation in the late stages, which results in dry, parchment-like hyperpigmented skin. Vitamin B complex combined with a diet rich in pellagra preventive foods is specific if the illness is not so far advanced that the patient cannot take the treatment. A lubricating cream makes the skin more comfortable.

The soles are frequently the sites of scabetic lesions in babies and small children. This fact is often over-

1. Nelson, L. M.: Symmetric Lividity of the Soles, Arch. Dermat. & Syph. 47: 822-825 (June) 1943.

2. Andrews, G. C.: Diseases of the Skin, ed. 2, Philadelphia, W. B. Saunders Company, 1938.

looked and an error in diagnosis made because the lesions are thought to be out of place. Scabies is one of the most perplexing cutaneous problems of the war. British literature since the war shows a huge increase in the number of articles on this disease. Many new and ingenious treatments have been tried. The overnight cures for scabies are generally unsatisfactory. Benzyl benzoate has proved most satisfactory in the British army and among English civilians during the war. It was given a fair trial at the Ancker Hospital and found less satisfactory than the compound ointment of sulfur which had been used for many years.

The feet are involved in many drug eruptions. They are affected in the exfoliative dermatitis caused by arsenic compounds, gold compounds and the barbiturates as well as in the erythema, urticaria and exanthems produced by acetophenetidin, quinine and other drugs; also in the pustular eruptions following the use of iodides and bromides.

Fixed drug eruptions may occur on the feet. These are caused chiefly by phenolphthalein, arsenic compounds, gold compounds and the barbiturates. The eruption appears as solitary or multiple patches of erythema or inflammation shortly after the drugs are taken. The lesions subside after each dose unless the drug is taken continuously. There is a distinct flare-up when the drug is taken again. As a rule each recurrence is more pronounced unless the dose is greatly reduced. Recurrences take place in the same spots, and new lesions appear as time goes on. The older lesions remain as brown pigmented patches long after the causative drug has been stopped, but the gross inflammatory signs disappear promptly when the drug is withdrawn.

Lichen planus is seen about the ankles, soles and dorsa of the feet. Here as elsewhere it is one of the most refractory diseases of the skin to treat. Fractional doses of superficial roentgen rays accompanied by intramuscular injections of $\frac{1}{6}$ grain (0.011 Gm.) of mercuric succinimide at weekly intervals are among the more helpful remedies.

Changes from erythema to gangrene can occur in several systemic diseases such as diabetes, syringomyelia and other diseases of the spinal cord. Ulcers occur on the feet in sickle cell anemia. No attempt will be made to discuss these changes here, but it should always be kept in mind that if the cause of an inflammatory condition of the feet is not specifically determined a general physical and laboratory examination must be done.

Certain dermatoses which are comparatively common elsewhere, such as dermatitis factitia and herpes simplex, can occur on the feet.

Some uncommon or rare diseases, such as necrobiosis lipoidica diabetorum, creeping eruption, schistosomal infections and the lymphoblastomas, may be represented by lesions on the feet.

Epidermolysis bullosa is a rare cutaneous disease in which vesicles or bullae are produced by slight trauma on the feet as well as other parts of the body.

Eczema of the feet is usually part of a local or generalized contact dermatitis or part of atopic eczema. The lesions vary from vesicles to scaling plaques accompanied by deep painful fissures. A discussion of eczema to be of any value would be too long for this paper.

Erythredema polyneuropathy (acrodynia) is manifested in swollen, pink feet, the skin of which later desquamates, and may appear as a vesicular dermatitis.

The exanthems scarlet fever, smallpox, chickenpox and vaccinia produce familiar lesions on the feet.

The chronic infectious granulomas syphilis, tuberculosis and leprosy all can appear on the feet in their many forms. Tuberculosis is probably limited to papulonecrotic tuberculids and the primary complex on the skin of the feet.

CUTANEOUS MANIFESTATIONS OF THE CIRCULATORY DISORDERS OF THE FOOT

RUBEN NOMLAND, M.D.

IOWA CITY

The most important cutaneous manifestations that occur on the foot in association with circulatory disorders are those which occur with peripheral vascular disease. In the past two decades the study of peripheral vascular disease has made great progress, and many physicians and clinics devote most of their time to the study of such diseases. The sources for this dissertation are several: standard textbooks on dermatology, books on peripheral vascular disease, other medical literature and the personal experience of the author and his colleagues who have a special interest in this phase of medicine. Specific statements in the literature or authorities will not be cited, and no attempt will be made to cover this vast field completely.

ARTERIOSCLEROSIS OBLITERANS

While arteriosclerosis occurs in both sexes, symptoms and signs of obliteration of arteries in the lower extremities occur almost always in men past the age of 55. The commonest symptom arises from intermittent claudication and consists of pain on exercise which disappears on resting. Pain during rest is not usually severe but there may be other sensations in the foot, such as coldness, paresthesia, "pins and needles" sensation and formication.

Local signs of vascular deficiency on the skin of the feet are the rule. Failure of the feet to sweat and loss of lanugo hairs over the toes are early signs of occlusive vascular disease. The nails may be atrophic and brittle, or they may be thickened and horny; corns and calluses may develop or may become much thickened.

Most important for diagnosis is the condition of the minute vessels of the skin as evidenced by the color of the skin. A purple-red color on dependence is the most important sign of arterial circulatory deficiency, which may indicate a compensatory dilatation of superficial vessels to make up for partial closure of the large vessels. The redness consists of a flush involving the sole of the foot, extending up the sides to some degree, and involving the dorsa of the toes and adjacent parts of the foot.

Blanching of the foot on elevation to the perpendicular is also present. The rapidity with which this blanching occurs is often an indication of the severity of the arterial deficiency. Return of normal pinkness as the foot is depressed to the horizontal also may indicate the degree of insufficiency; the more nearly horizontal the leg is when pinkness returns the greater the insufficiency. A

From the Department of Dermatology and Syphilology of the University Hospitals, State University of Iowa. "Cutaneous Disorders of the Feet," is published under the auspices of the Section on Dermatology and Syphilology.

similar and probably more accurate estimation of arterial deficiency can be made by having the patient alternately flex and extend the toes; rapid blanching with slow return of the normal pink color is present in occlusive vascular disease.

If the deficiency has attained the level of producing clinical symptoms, then the superficial pulses of the dorsalis pedis and posterior tibial arteries are usually absent or much decreased. At room temperature there is decrease in the surface temperature of the affected foot. X-ray examination using soft tissue technic may show calcification of arteries, but negative findings do not exclude occlusive disease, and presence of calcified vessels does not necessarily indicate vascular deficiency. Oscillometric readings give reliable information as to the status of the arterial supply. The equipment does not cost much more than a good sphygmomanometer, and the method of use is now such that the average physician can employ it effectively. Other tests, suitable only for those specially interested in peripheral vascular disease, have been devised to determine the degree and the amount of vascular closure.

The foot with deficient arterial circulation is much more severely affected by slight trauma or infection than the normal foot, so that apparently minor conditions may be extremely serious. Minor blisters, abrasions, ingrowing nails, corns, calluses, fungous infections and other simple disorders may be the source of intractable infection or even gangrene. All these conditions should be prevented or if present should be treated conservatively and carefully.

Gangrene is the most serious event which can occur in the foot with deficient arterial circulation. It may start as a dry gangrene involving the distal parts, most commonly the tips of the toes, particularly the great toe, but be progressive even to involving much of the foot.

Moist gangrene is usually the result of infection of a preceding lesion, such as an ingrowing toe nail, a blister, a corn or a callus. It is often preceded by more intense vascular phenomena plus the signs of inflammation, and it spreads more rapidly than the dry type. Ulcers of the mal perforans type with much destruction of the deeper tissue are apt to occur on the sole, particularly near calluses. The ulcer externally may be evidenced only by a fissure or a small granulation, while x-ray examination may show massive destruction of bone. In patients who are confined to bed decubitus ulcers on the heels are common unless precautions are taken to avoid them.

The older person with diabetes is prone to sclerosis of the arteries and subsequent damage to the foot which is in no way different from arteriosclerosis obliterans. In the diabetic patient the conditions are apt to be more serious.

THROMBOANGIITIS OBLITERANS

Thromboangiitis obliterans is an obliterative arterial disease of unknown cause in which there are often superficial migratory phlebitis and vasospastic phenomena associated with the inflammatory thrombosis. It occurs at ages from 25 to 45, almost exclusively in men, and affects predominantly the Jewish race. Pain from intermittent claudication is common and severe. Other types of pain also occur with exercise, and pain during rest is often present and may be severe.

Signs of vascular disturbance on the feet are more pronounced than in arteriosclerosis. There is rubor which may be very intense on dependence, extending onto the top of the foot, the toes and the sides. Ischemia on elevation also occurs. In some patients there is vaso-spasm followed by dilatation and cyanosis on exposure

to cold. On examination there is usually a decrease or an absence of pulse in the superficial arteries of the foot and frequently in the arteries at the wrist. The surface temperature is reduced. Trophic disturbances of the skin, disturbances of the nails, calluses, blisters and other findings similar to those discussed in arteriosclerosis obliterans are usually present. Gangrene is common in the later stages and usually involves the toes and follows one of the aforementioned conditions, occurring particularly after the formation of a blister or about a corn or an ingrowing nail.

The treatment of arterial occlusive diseases of the extremities has made great progress in the past several years. Prophylactic care of the feet in the early stages may prevent one of the more serious sequelae. Well fitting stockings of cotton or thin wool and properly fitted shoes of soft leather are the first essentials. The feet may be washed as often as required but not more than once a day with a mild soap and warm water. They should be dried gently and carefully. If the skin is dry a vegetable cooking oil may be rubbed into it. Nails should be trimmed with care not to injure the skin and should be cut straight across. Ingrowing nails should be treated by a physician. Corns and calluses should be treated with respect, and salicylic acid plasters should not be used. Any blister, bruise, cut or injury should be treated carefully and conservatively. Exposure of the feet to cold should be avoided, as should also all constrictions of the legs, such as garters. Excessive standing, sitting with legs crossed and exercise which causes pain should be eliminated. External heat from lights or hot water bags had best be avoided, as it may cause trouble by increasing the metabolism of the part without adding to the blood supply. Bed stockings may be used to help cold feet. Midday rest with feet slightly elevated or mild exercises of the type described in the following paragraph are often helpful in aiding the circulation.

More active treatment may be carried out if the symptoms warrant it or if a minor complication is anticipated. Rest in a horizontal position requires less peripheral circulation and is helpful. Vascular exercises done as follows in each of three positions will aid in establishing collateral circulation: The feet are plantar flexed, then dorsiflexed, the toes are turned inward and then outward; then the toes are spread widely, then closed. This exercise is carried out (1) with the feet on a board at an angle of 30 degrees or less above the horizontal for two minutes, (2) with the feet hanging over the edge of the bed for three minutes and (3) with the feet horizontal and covered with bed clothes for five minutes. Up to three sessions a day of such exercises may be carried out.

More or less elaborate apparatus can also be used. Among them is one by which alternate suction and pressure can be exerted on the foot enclosed in a glass boot for periods of an hour or more and a total of one hundred hours. This procedure under the designation passive vascular exercise was popular several years ago. Periodic venous occlusion by means of an inflatable cuff similar to that used for taking blood pressure has also been used, but the apparatus is not simple. Passive exercise produced by means of an oscillating bed is one of the best methods, but the bed is expensive.

Heat used with caution and applied usually to adjacent areas rather than to the affected leg and foot is useful. It may be obtained by hot sitz baths, short wave diathermy to the pelvic region or the application of heat to an uninvolved leg. Heat over 94 F. is probably harmful to an affected leg.

Drugs which act as vasodilators may be helpful. Among these are alcohol, sodium nitrite or erythrol tetranitrate, papaverine hydrochloride intravenously several times a day and drugs of the xanthine type.

Elevating the temperature by means of typhoid vaccine in doses of 25 million killed organisms given intravenously at intervals of several days to a week or more may improve the circulation. The intravenous injection of 2 to 5 per cent sodium chloride solution in amounts of 250 cc. three times a week for months has been used in the therapy of thromboangiitis obliterans. Iontophoresis with mecholyl chloride or histamine, which produce vasodilatation, has also been used.

In the presence of gangrene amputation will usually be necessary, and it may be difficult to decide the level at which it should be performed. Amputation of digits or of a part of the foot is apt to require reamputation. Recently refrigeration of the extremity has controlled infection and made a most satisfactory anesthesia for amputation; it allows the surgeon to pick the optimal time for amputation.

ACROCYANOSIS, CHILBLAIN CIRCULATION, PERNIO, ERYTHROCYANOSIS CRURUM PUELLARIS

The disorders thus grouped, probably essentially the same except for the degree of involvement, have in common mottled cyanosis of the extremities, lowering of the surface temperature, aggravation of symptoms during cold weather and susceptibility to certain more definite clinical syndromes. Disorders of this type are much more common in women and are particularly evident in adolescent girls. The purple-red mottling is caused by stasis of blood and loss of oxygen from the blood in the capillaries and the venules of the skin. The pattern is caused by the arborizations of the capillary supply of the skin. There is probably a large element of vasospasm in the cause of the condition but in the more advanced or complicated forms there is added vascular inflammation with stasis, giving rise to indefinite infiltrated plaques, superficial ulceration and other lesions.

The diagnosis of this condition is not difficult. The feet are cold and clammy with cold perspiration, and the skin may be macerated from the sweating. The purple mottling with occasional white areas, aggravated by cold, is distinctive. The legs, hands, arms, nose and ears are usually the sites of similar circulatory changes.

Patients with these disorders are reputed to be more susceptible to other conditions, such as erythema induratum, lupus pernio, other inflammatory lesions of the legs occurring in winter, neurocirculatory asthenia, chronic rheumatoid arthritis and probably some forms of mental disease. Whether livedo reticularis should be considered as an advanced or severe form of one of the aforementioned disorders or a separate condition is difficult to say. In this disorder the purplish mottling follows a larger pattern, areas of livedo are more prominent and small superficial dry gangrenous ulcers of the legs and toes may occur.

Chilblains, or pernioles, are painful or burning indurated reddish purple swellings that on the feet may be located over the toes, on the plantar surfaces, especially the heels, but not on the insteps. They may occur in normal persons who are exposed to damp cold over long periods or they may occur as a result of frostbite. They occur often in patients with acrocyanosis even though exposure to cold is minimal. The lesions usually disappear in summer and return in the fall with the onset of cold weather. They may become semipermanent in some, particularly if there is a background of infection

such as tuberculosis. Similar lesions occur on the hands, the nose and the ears in the same type of person.

The treatment of the disorders grouped as acrocyanosis consists chiefly in the avoiding of exposure to cold, particularly damp cold. Warm stockings and loose fitting soft shoes should be worn. Excessive perspiration may be guarded against somewhat by soaking the feet in warm potassium permanganate solution of a strength of 1:1,500. Aluminum chloride in a concentration up to 25 per cent painted on the sweating areas one night a week frequently decreases the perspiration considerably. X-rays should not be used, as damage to the skin occurs before permanent decrease of sweating does. In the severe forms with excessive cyanosis, areas of ulceration or other complications of a vasospastic nature, lumbar sympathectomy may be necessary.

RAYNAUD'S SYNDROME

Raynaud's syndrome is a vasospastic disorder without vascular occlusion characterized by vasomotor phenomena of the extremities, superficial dry gangrene and trophic disturbances, with fairly characteristic findings in the capillary bed. Over 95 per cent of the patients are women, mostly in the age group of 17 to 35.

The vasomotor signs are the essential feature of the syndrome. Rather suddenly, precipitated by cold or emotional disturbances, the tips of the digits become pale and exsanguinated. In the beginning of the attack the spasm of the vessels is intermittent and can be seen best in the finger nails, where there will be alternate waves of whiteness and pinkness of the nails, but when the digits become bloodless the nails are similarly affected. The phase of local syncope is followed after a period by a cyanotic phase that appears slowly and lasts longer. The digit affected becomes gradually bluish, then purplish and finally blue-black. After some time the normal color returns. If the condition is on the feet not all the toes may be affected, and one digit may be in the phase of syncope while others may be cyanotic. There are subjective sensations which vary from itching, burning and other minor sensations to excruciating pain during an attack. Usually the hands are more severely affected than the feet.

The phase of trophic disturbances does not appear in all cases. It affects the extremity of the involved digit. After a severe attack of syncope or repeated minor attacks a small phlyctenular blister appears on the most distal part of the digit; this is followed by a small painful necrotic ulcer, which is usually dry and heals slowly, leaving a slight scar. After repeated episodes of superficial gangrene there is a loss of substance of the tip which may involve the bone of the terminal phalanx. Changes in the nail, both hypertrophic and atrophic, are the rule, and the nail grows over the end of the affected digit. The skin may be atrophic, thin and shiny or in a few it may become infiltrated and sclerodermatous. Extensive gangrene is uncommon but may occur.

The surface temperature of the extremity is lowered, and cold clammy perspiration is usually present. The superficial pulses are normal, but microscopic study of the capillaries of the nail fold may demonstrate a spasm of the vessels fairly diagnostic of Raynaud's syndrome.

Acrosclerosis (sclerodactylia, scleroderma with sclerodactylia) has been definitely separated from the group of diffuse sclerodermas as a different type of cutaneous sclerosis. In this disorder there are for a long time signs of acroasphyxia of the Raynaud type on the extremities. As in Raynaud's syndrome the hands are

worse and more often affected than the feet. Following the vascular symptoms there is sclerosis of the skin and underlying tissues involving first the digits and then gradually the feet and legs, the hands and the arms. The face, the upper part of the chest and the back are also involved in the sclerotic process. Atrophic changes, loss of distal phalanges, changes in the nails, necrosis and occasionally local calcification occur. Acrosclerosis cannot always be differentiated from Raynaud's syndrome with secondary sclerosis of the cutaneous tissues.

Treatment of Raynaud's disease and acrosclerosis is unsatisfactory. Avoidance of exposure to cold is most important, and it may be advisable for the patient to move to an equable warm dry climate. Vasodilatation obtained by means of drugs such as nitrites or papaverine hydrochloride may help. External heat of moderate degrees and light massage may aid. Iontophoresis of mecholyl chloride has been suggested as one of the best therapies. Lumbar sympathectomy offers a possibility of relief that may be permanent. It should be done before permanent damage has taken place. In late stages of Raynaud's disease and in acrosclerosis it is of little value.

ERYTHROMELALGIA

Erythromelalgia is a disorder of the extremities characterized by redness, increased surface temperature and pain. It involves the feet more often and more severely than the hands. An attack is provoked when the surface temperature reaches a critical level, though there are other factors, such as dependence, which also have an effect. A burning, sticking, prickling type of pain is constantly present. The surface temperature is elevated and the foot is red because of the vasodilatation, which is of the active type. The more distal areas of the foot, such as the toes or the heel, are most involved and there may be swelling, but only rarely are there trophic changes.

On examination the increased heat and redness are evident and the pulses are full and bounding. These findings serve to distinguish this disorder from occlusive arterial disease of Raynaud's syndrome. Owing to redness, swelling and pain in attacks, gout must be first considered in differential diagnosis. Treatment is not satisfactory. Heat and dependence should be avoided. Acetylsalicylic acid may control the symptoms.

IMMERSION FOOT, TRENCH FOOT, SHELTER FOOT

Prolonged refrigeration at temperatures near freezing and dependence of the feet, which are frequently wet and encased in tight coverings, give rise to serious vasomotor damage in the foot. In this war the condition occurs mostly in those torpedoed in the north Atlantic; in the first world war it occurred in men standing in damp trenches—circumstances which have given the aforementioned popular names to the syndrome.

When the affected person is taken from the lifeboat the feet are cold, swollen and white, with scattered cyanotic areas. The feet are numb and heavy and are anesthetic to pain, touch and changes of temperature. If the feet are allowed to "thaw," there is rapid development of swelling and the feet become red and hot. The peripheral parts become swollen and livid, and, as the condition progresses, blisters, filled either with clear or bloody fluid, and gangrene may be imminent. In severe involvements gangrene occurs soon after thawing, but the minor ones may show only slight redness, edema and slight sensory changes. Because of damage to the sympathetic and other nerves, there is no sweating of the affected feet, and this may account for the redness, heat and rapid swelling that occur with quick thawing.

The greatest progress in the treatment of this condition has been the demonstration that surrounding the limb with ice or keeping it cold by other methods will prevent serious damage except in severe types. In the first aid stage care in removing the patient to a hospital and avoidance of heat and dependence of the foot are extremely important. Refrigeration of the elevated leg relieves the pain and prevents swelling and blister formation. It may need to be kept up for a week or longer.

Following recovery from the acute phases pain, redness, edema and other manifestations of a circulatory disturbance often persist, and troublesome neuritis often occurs.

Severe or mild repeated frostbite of civilians is in essence no different from immersion foot. In northern climates the layman has for years carried out refrigeration for minor frostbite. It is interesting to see that this treatment is equally effective in severe frostbite.

Late changes following frostbite, particularly such severe ones as gangrene, may not be caused by the freezing itself but may be due to the activation of arteriosclerotic occlusive disease or thromboangiitis obliterans in a person with subclinical manifestations. Intolerance of cold, chilblains and mild vasomotor changes of the feet are common after-effects of freezing and persist for years.

VASCULAR ANOMALIES

Port wine or capillary angioma occurs on the foot, usually as part of an extensive port wine mark. The involved skin, apparently normal except for the purplish color and possibly slightly increased surface temperature, is easy to recognize. Occasionally angioma of this type is part of an extensive deep vascular nevus. No treatment of capillary angioma is effective.

Spider nevus is found on the foot, where it may be multiple. The central capillary with radial spokes is characteristic. Fulguration or closure of the central vessel with a galvanic current is usually successful.

Small cavernous angiomas similar to the mulberry marks found so commonly elsewhere also occur on the foot and toes. They appear as pea to quarter size (24 mm.) localized vascular lesions. The small ones are successfully treated with solid carbon dioxide; the larger ones require irradiation with x-rays or radium.

A cavernous angioma with or without port wine elements may be of large size on an extremity. Often such an angioma allows short circuiting of the arterial blood to the veins. In such cases there are frequently overgrowth of the extremity, increased surface temperature, arterial blood in the veins, which may pulsate, and even cardiac signs of the shunting of the blood. Cirroid aneurysm is somewhat of this type. A large angioma may require operative removal or even amputation if arteriovenous communications are numerous.

Lymphangioma may be of the circumscribed type which presents itself as a localized area of pseudovesicle formation, frequently in an elevated verruca-like area. If the skin over the lymphangioma is broken, lymph may ooze for a long time. Local destructive procedures, such as biterminal diathermy or cautery, give good results.

Diffuse lymphangiomatosis of the leg and foot is not common but is serious because of the increase in size of the extremity and the proliferation of interstitial tissue giving rise to deformity. Local gigantism may also be present here. Treatment is not satisfactory.

University Hospitals.

FUNGOUS INFECTIONS OF THE FOOT

MARCUS RAYNER CARO, M.D.

CHICAGO

The modern habit of wearing shoes that encase the foot has endowed the surface of the foot with the warmth and moisture that make it an excellent culture medium for the growth of fungi. Pathogenic fungi have no doubt always made the foot a site for various cutaneous infections, but it is only in recent years that such infections have attracted dermatologic interest. Ormsby and Mitchell¹ in 1916 made the first comprehensive report in the United States of a large series of cases in which fungi were demonstrated microscopically. Since then fungous infections of the foot have increased to become among the most common cutaneous disorders. Direct microscopic examination of scrapings and the use of cultural methods for demonstrating the presence of fungi have made it possible to recognize many cases that might otherwise have been misplaced under some other diagnosis. Unquestionably, however, there must in addition have been a tremendous increase in the actual incidence of cases. The mobilization of millions of men incident to World War I inadvertently distributed many cases of fungous infections among the various camps and training centers. These cases acted as reservoirs from which the infections spread to great numbers of previously uninfected feet. Demobilization was followed by the dissemination of pathogenic fungi by the men returning home, and fungous infections of the foot have remained endemic in all parts of the United States since that time.

THE SUPERFICIAL MYCOSES

Dermatophytosis.—The most common fungous infection of the foot is that caused by the many species of ringworm fungus and described under many names, such as tinea, eczematoid ringworm, epidermophytosis, epidermonycosis and trichophytosis, all of which may comprehensively be designated by the term dermatophytosis.

Many genera and species of fungi may produce dermatophytosis. Weidman² in 1926 listed the geographic distribution of cases and showed that different fungi predominate as the etiologic agents in different parts of the world. According to Lewis and Hopper³ *Trichophyton gypsum* and *Trichophyton purpureum* are the most frequently reported causative fungi at present, while *Epidermophyton inguinale* and other fungi are found less often. Not only do fungi vary in their geographic distribution from year to year, but they may also show great differences in virulence at various times.

The disease may appear at any age, but it is seen relatively seldom in children. Men have been affected more often than women, but this is probably the result of factors which may operate less often in the future. Because of mobilization in army camps and greater tendency to visit gymnasiums and swimming pools, men more often than women have in the past been exposed

to infection. Woman's increasing role in industrial activities and in the prosecution of the war should do much, however, to afford her an equal opportunity for such exposure. It remains for the future to prove whether men are actually more susceptible to infection.

The infection may appear on a previously healthy skin, either with or without a preceding injury. Contact with material contaminated with fungi, such as socks, shoe leather, bath mats or wet floors, often precedes the infection. A certain predisposition to the disease, however, must play an important role, for, as White⁴ pointed out and as has recently been shown in a statistical study by Sulzberger and his co-workers,⁵ conjugal and familial transmission of the infection is uncommon. In most cases the patient carries his own dormant reservoir of fungi somewhere on the foot, and when his general resistance is lowered or the local conditions on the foot become optimum for the growth of fungi an active infection may flare up. Cases of dermatophytosis of the foot are seen through all seasons of the year but in this climate they tend to increase in number and severity in the summer.

Dermatophytosis of the foot may present a variety of clinical pictures. Most of these may be included in the classification of intertriginous, vesicular and hyperkeratotic groups. In most patients in whom the infection is minimal it consists of a macerated scaling between the toes, especially in the interspace between the fourth and fifth toes. With increased activity of the infection the scaling may spread to involve all the interspaces, although the space between the large and the second toe is seldom affected. There may be increased moisture, the surface often becomes sodden and erythematous, and at times fissures may appear in the interspaces and on the basal plantar surfaces of the toes, especially that of the fifth toe. Itching is usually present and often severe, while in the presence of fissures pain is an outstanding symptom.

In some cases vesicles appear on the sides or the under surfaces of the toes, and at times there are vesicular patches on the soles, especially on the insteps. Such acute attacks may appear on previously uninfected feet but more often they complicate intertriginous infections which may have been irritated mechanically, as by scratching, by increased perspiration or by overtreatment. The vesicles are usually deeply set and tense, and they often become sufficiently large to make walking difficult. When small the vesicle may dry spontaneously and result in a dry scale which soon exfoliates to leave a slight collaret. In most cases, however, the larger vesicles rupture to release a mucilaginous fluid and to expose a smooth, bright red base. Often the contents of the bulla become purulent and a red inflammatory areola develops. Such lesions do not tend to rupture spontaneously, and the removal of the roof of the bulla exposes a deeply excavated, red, granular multilocular base. At times groups of vesicles may coalesce to form patches of varying size. These patches characteristically have a sharply outlined border which is often serpiginous and which shows an overhanging peripheral scale. The center may become covered by epithelium or it may be the site of fresh vesicular outbreaks. Itching in these conditions is usually severe, and it often leads

patients to tear the vesicles open or to puncture them, procedures which are sometimes followed by secondary infection. In the intertriginous and the vesicular forms there is a tendency for both feet to be involved, but it is not uncommon for one foot to be severely inflamed while the other may be entirely well or show but a minimal infection.

In the chronic hyperkeratotic type the involvement is usually bilateral and often symmetrical. Any part of the plantar surface may be affected, the involved areas ranging from a small patch on the instep or heel to the entire sole. In such cases the dermatophytosis often begins with vesicles, but eventually there are produced sharply outlined patches in which the horny layer is uniformly thickened, with no tendency to central clearing. The scale is grayish and dry, and it may show variations in thickness even to forming a shell-like coating. At times fissures may occur within these patches and extend deeply into the underlying flesh, producing intense pain. Lewis and his associates⁶ have shown that a specific clinical picture of infection is produced by *T. purpureum*. Vesicles or acute inflammation practically never occur. Usually there are sharply outlined patches involving from a small area to the entire sole. In the cases of

Fig. 1.—Acute vesicular dermatophytosis on the foot.

greater involvement the infection extends up on the sides of the foot and about the heel. The infected skin is dull red, with fine branny scaling and no tendency toward central clearing. Itching is commonly present.

The nails may be infected by any of the ringworm

oi. The infection commonly begins under the free margin of the nail or at the sides as a grayish or dark accumulation of scale and debris which lifts the nail away from the nail bed. Linear streaks of this debris extend posteriorly toward the nail root, and the overlying nail becomes opaque and yellowish, and at times greatly thickened. One or several nails may be affected. In infection by *T. purpureum* the progress of the disease is slow but there is a tendency for the infection to spread gradually to involve all of the nails. The separation of the nail from its bed proceeds backward from the free margin, and the loose part of the nail becomes thin and brittle. Eventually it is shed, exposing an opaque rough surface that is irregularly ridged and that extends to a shrunken proximal stump of the nail. Paronychia is not ordinarily seen in these cases. Infection of the nail may persist long after all other clinical evidence of the disease has disappeared. In this stage the nail may then harbor in a dormant state the fungi from which active dermatophytosis may later develop.

The clinical pictures described in the foregoing paragraphs may be complicated by various developments. Scratching or puncturing the vesicles may be followed by secondary infection, although at times pustules develop without apparent preceding trauma. These pustules are often the portal of entry for bacteria which produce streaks of lymphangitis which may extend upward on the leg and thigh and result in regional lymphadenopathy. At times cellulitis may develop about the pustules, and this may extend to the dorsal surface of the foot and cause great swelling, pain and fever. Not infrequently erysipelas-like patches occur on the dorsal surface of the foot and on the leg, and these are introduced by chills and fever identical with the symptoms that accompany erysipelas on any other parts. This type of lesion has been variously explained as an allergic reaction to the fungus infecting the feet⁷ or as an actual streptococcal infection⁸ in which the portal of entry is often an interdigital fissure resulting from dermatophytosis. Exacerbations in the fungous infection of the feet are often followed by recurrences of these erysipelas-like attacks. Patches of dermatophytosis may appear on areas adjacent to the foot by direct extension or the infection may be implanted on other moist areas such as the groins, the axillas and the region about the anus. Not infrequently, however, eruptions occur on distant parts which are caused by hematogenous transmission of the fungus or its toxins from its original focus on the feet to sites previously sensitized, on which there develops an allergic "id" reaction.⁹ The most common secondary site for the dermatophytid is the hand. There the lesions occur as small vesicles on the sides of the fingers or often as small or large, deep, tense vesicles on the palms. Fungi ordinarily cannot be demonstrated in these secondary vesicles on the hands. Occasionally dermatophytids may be generalized and may take the form of lichenoid lesions, eczematous or psoriasiform patches, erythema multiforme-like lesions or urticaria. Often the development of the "id" reaction is initiated by overtreatment of the original infection on the foot.

The diagnosis of dermatophytosis can generally be made on the appearance of the lesions. Fungi can be demonstrated in most cases by a microscopic examination of the scale or the vesicle fluid prepared with a 10 per cent solution of potassium hydroxide. It has become fashionable to diagnose most dermatoses of the foot as "athlete's foot," and one should always search for and demonstrate the fungus before accepting the diagnosis. Differentiating the fungi by cultural methods is of aid in determining the prognosis of an individual case, for infection by *T. purpureum* is much more resistant to treatment, and it should receive more drastic measures. Diagnostic testing with trichophytin is of little value, for a positive reaction demonstrates merely that an infection has at some time been present. Dermatophytosis must be differentiated from many disorders of the foot. In the acute forms it may be confused with dermatitis due to external irritants such as shoe dyes or at times formaldehyde used prophylactically. The disease may in some cases be simulated by monilia, dyshidrosis, pustular psoriasis, pustular

bacterid,¹⁰ streptococcic infection,¹¹ chronic eczema and psoriasis. While the differentiation from these dermatoses can often be made on clinical grounds, the most valuable differential finding in dermatophytosis is the fungus. The hyperkeratotic form may at times resemble tertiary syphilis, but in that infection the lesions are nearly always unilateral and never symmetrical. Onychomycosis may be simulated by the nail changes seen in psoriasis. In the latter, however, there are often diagnostic lesions present on other parts and fungi are never found in the scrapings. To demonstrate the fungus in nails infected with *T. purpureum* it is necessary to scrape the nails quite deeply.

In the prophylaxis of dermatophytosis efforts should be directed chiefly to preventing activation of the dormant foci of infection that are present on most feet. Feet should be bathed often and dried thoroughly, socks should be changed frequently, and shoes must be permitted to dry well after wearing. Dusting powder used regularly between the toes and in the socks helps to absorb the perspiration and to keep the feet dry. To protect against contracting an extraneous infection one should never walk barefooted on damp floors or wear shoes or socks that may have been contaminated with pathogenic fungi. Contaminated socks should be boiled, and shoes should be fumigated with formaldehyde vapor after each wearing.

The many systems of treatment and the great number of drugs recommended indicate that there is no specific cure for dermatophytosis. While it is relatively easy to destroy fungi in the test tube, on the foot it is more important to adapt the treatment to the clinical state of the dermatosis rather than to the particular species of fungus present. In cases of mild intertriginous infection the use of antiseptic dusting powders, such as borated talc with the addition of 2 per cent salicylic acid, or mild tincture of iodine, may be effective. In acute vesicular cases great relief may be obtained by removing the tops of the vesicles with scissors and applying continuous cold wet dressings of a 1:4,000 aqueous solution of potassium permanganate or a 1:16 dilution of solution of aluminum acetate. Such wet dressings tend to allay the inflammation and to reduce the hyperhidrosis which generally accompanies these infections. In cases of severe infection it is advisable to keep the patient off his feet, and in these cases the wet applications are preferable to foot baths which necessitate holding the feet dependent. Instead of using strong antiseptics in such acute conditions, it is best to disregard the fungous cause for the time being and to treat the infection as an acute dermatitis.

When the acuteness of the process has subsided, stronger measures may be introduced. Fissures may be painted with a 5 per cent solution of silver nitrate. Foot baths in a 1:4,000 solution of potassium permanganate may be continued, and in addition keratolytic agents, such as diluted ointment of benzoic and salicylic acid, may be applied. Mild tincture of iodine may be used or any of the dyes that are recommended as fungicidal agents, such as 2 per cent gentian violet solution or Castellani's paint. In cases of the chronic hyperkeratotic form stronger medication is often necessary, but the strength of the drugs used should not be increased more rapidly than the tolerance of the

skin will permit. Ointment of benzoic and salicylic acid to which 1 per cent thymol has been added is a time honored remedy, and ointments of phenylmercuric nitrate (1:1,500), crude coal tar (1 to 5 per cent), anthralin (dihydroxyanthranol) (0.1 per cent to 1 per cent) and chrysarobin (1 to 10 per cent) are often useful. Roentgen rays are in general use in treating the chronic infections, and they form a valuable adjunct in the treatment of dermatophytosis. The use of camphor-phenol mixtures is at times followed by burns, and the benefits to be derived are hardly worth the risk. Biologic therapy with trichophytin has generally proved disappointing.

The treatment of infected nails produces at best but slow improvement. In cases caused by *T. purpureum* the prognosis is nearly hopeless. The various reme-

dies used include ointment of benzoic and salicylic acid, 6 per cent salicylic acid and 12 per cent benzoic acid in alcohol, and Castellani's paint. The surface of the nails should be scraped before any medication is applied. Roentgen rays should be used cautiously. Removal of infected nails on the feet is not advised, for the new nails tend to be reinfected.

Moniliasis.—Moniliasis is an infection of the skin caused by a yeastlike fungus, *Monilia albicans*.¹² This fungus is often present normally in the gastrointestinal tract, but when present on the skin it is generally pathogenic. The resistance of the skin to monilial infection is greatly lowered by maceration. Obese persons, in whom intertrigo is common, often suffer from this disease, while profuse sweating or prolonged immersion in water, as in water baths, is frequently

12 Hopkins, J. G.: Moniliasis and Monilids, *Arch. Dermat. & Syph.* 25: 599 (April) 1932.

followed by moniliasis. This predilection is greatly increased in diabetic patients.

Moniliasis may affect many parts, as in the clinical forms of *erosio* between the fingers, as in *perlèche*, as in intertrigo on the axillas, groins, anal fold or under the breasts, as in vaginitis, as in thrush, or it may become generalized. When the foot is involved, the lesions are often found in the spaces between the toes as shiny red moist patches of intertrigo that are sharply outlined. The patches spread by peripheral extension and are surrounded by many outlying inflamed small macules or vesicopustules. In time there may develop large, circumscribed, bright red, oozing patches that cover much of the dorsal surface of the foot. There is no tendency to central clearing. One or both feet may be involved. Itching may be present, but most patients complain of a burning sen-

Fig. 3.—Monilia intertrigo on the foot.

sation, especially after contact with water. An "id" reaction may develop, especially following overtreatment, and the moniliid may become generalized.

The nails are often affected, either primarily or as a complication of the infection of the skin. An injury such as may occur in manicuring often precedes the infection. One or several nails may develop paronychia with a bolster-like swelling accompanied by acute symptoms of erythema, tenderness and at times throbbing pain. The proximal portion of the nail becomes irregularly roughened and depressed at the site of the infection, and frequently the sides of the nail become darker and thickened. As the nail grows out the pathologic changes move distally as a transverse band. In chronic infection the entire nail becomes involved in time, or it may be shed; the prognosis for the regrowth of a normal nail, however, is good.

The diagnosis of a monilial infection can usually be made on the clinical appearance of the circumscribed, bright red, oozing patches. The intertriginous

form must be differentiated from dermatophytosis, streptococcic dermatitis and dermatitis caused by the use of strong local medication. Monilial paronychia is not very painful, and it does not yield pus on incision as would a pyogenic infection. The most important diagnostic finding, however, is the causative fungus. This cannot always be demonstrated on direct microscopic examination, but cultural methods are generally successful in proving the diagnosis.

In treating moniliasis it is important in every case to rule out the presence of diabetes mellitus. In patients with diabetes strict control of that disease must be accomplished before any improvement in the monilial infection can be produced. Almost specific in the local treatment of monilial infections of the skin and nails is a 1 per cent aqueous solution of gentian violet. Roentgen rays are beneficial, especially in paronychia. Ammoniated mercury ointment (3 to 5 per cent) is often effective. While in some cases cold wet dressings of a solution of potassium permanganate (1:4,000) reduce the inflammation and oozing, good results are more often obtained by keeping the infected parts dry. Soap and water should not be used, and the foot should be dusted frequently with borated talc or with powdered starch.

THE DEEP MYCOSES

Mycetoma.—The only fungus infection involving the deeper tissues that shows a predilection for the foot is mycetoma, or Madura foot. This disease, endemic in India and parts of Africa, is rare in the United States, only about 24 cases having been reported, chiefly from the Southwestern states.¹³ Many fungi have been reported as being the cause of mycetoma,¹⁴ among them *Actinomyces* and *Madurella*. Most cases have been seen in men who worked barefooted on the farm, and the fungus was supposedly introduced into the deeper tissues of the foot through an injury. After an incubation period varying from one month to several years a small red nodule appears at the site of injury, most often on the plantar surface of the foot. The nodules enlarge, soften and break open to discharge a yellowish, blood streaked viscid fluid containing granules. By the color of these granules cases of mycetoma formerly were classified into grayish, red and black varieties, but such a division overlooked the fact that granules of the same color may be produced by different fungi. From each open lesion a sinus penetrates deeply into the foot, and these sinuses do not heal. New nodules appear, enlarge and open, and after many years the foot becomes bulbous and its entire surface covered by bullae and pustules. Each of these includes the opening of a channel that penetrates deeply through soft tissues to the bones, eventually resulting in osteomyelitis. The foot becomes greatly deformed and useless, while the leg becomes atrophic. Pain is generally absent, there is no especial effect on the general health, and the course of the disease is very chronic.

In cases of advanced infection the appearance of the bulbous foot is diagnostic. Earlier in the course of the disease the diagnosis can be made from the discharged granules resembling fish roe and by the microscopic demonstration of the fungus in these granules.

In the early stages treatment with large doses of potassium iodide may be helpful, but in most of the

14. Gammel, J. A.: *The Etiology of Madurellosis*, Arch. Dermat. & Syph. 15: 241 (March) 1927.

reported cases cure was finally obtained only by amputation of the infected foot.

Sporotrichosis.—Cases of sporotrichosis have been reported from many parts of the world, especially France. In the United States most of the recorded cases have occurred in the region of the Mississippi Valley. *Sporotrichum schenckii* is the fungus most often demonstrated in our cases, and it is widely distributed in the excreta of human and animal carriers and on many plants. The disease affects not only man but horses, mules, dogs and rats.

Infection has been shown in some cases to follow an injury with a thorn¹⁵ through which the fungus was introduced into the skin. Gardeners and farmers are especially prone to contract this disease. In the localized lymphangitic type of sporotrichosis, which is the one most commonly seen here, a lesion develops at the site of injury after an incubation period of about a week. This "sporotrichotic chancre" is an indolent nodule which in most cases ulcerates, and at times it may be indurated and resemble the primary lesion of syphilis. It occurs most often on the finger or the hand, but it has been described also on the foot and other parts. About a week or longer after the appearance of the primary lesion a linear chain of indurated subcutaneous nodules appears along the course of the lymphatics ascending from the site of infection, and the lymph vessels become thickened and cordlike. These nodules enlarge, become attached to the skin and generally ulcerate to discharge a grayish yellow pus. The ulcers sometimes heal slowly but in most cases they persist indefinitely. The regional lymph glands are not enlarged, and there are no constitutional symptoms. Other types of sporotrichosis are the disseminated subcutaneous type which is often seen in France, the disseminated ulcerating type¹⁶ and the systemic type.

The diagnosis is generally made on the appearance of an ulcerating nodule at the site of an injury to the skin followed by the development of a chain of indolent subcutaneous nodules. The disease must be differentiated from other deep fungous infections and from tularemia, tuberculosis, syphilis and pyogenic infections. The diagnosis can be established by demonstrating the sporothrix on culture, by animal inoculation (rat) or by complement fixation and agglutination tests.

The use of potassium iodide in large doses is specific in sporotrichosis, and local roentgen treatment hastens the involution of the lesions.

Blastomycosis.—Blastomycosis may at times involve the foot. The causative fungus in cases seen in the United States is *Blastomyces dermatitidis*.¹⁷ A great majority of the cases have been reported from the Middle West, especially from Chicago. The lesion begins as a small papulopustule, which soon becomes crusted. It enlarges gradually by peripheral extension to produce sharply outlined patches, limited by a rounded or polycyclic border. In a large patch there is a separation of the lesion into definite zones: In the center lies an irregular whitish depressed atrophic area. About this is a wide zone in which the surface is papillomatous and either bathed by a seropurulent

discharge or covered by a thick adherent crust. The border is sharply demarcated, and it slopes abruptly from the warty zone to the surrounding normal skin. The border is violaceous red, shiny, and covered by many minute abscesses. The lesions may be widespread, and in some cases the infection may become systemic as well.

The diagnosis can be established by microscopic examination of a potassium hydroxide preparation of pus obtained from a small abscess in the border. Microscopic examination of the tissue will also demonstrate the blastomycetes within the giant cells present in the granuloma. Blastomycosis must be differentiated from tuberculosis verrucosa cutis, tertiary syphilis, bromoderma, sporotrichosis and epithelioma. This differentiation may be accomplished most conclusively by demonstrating the fungus.

Treatment may at times be successfully carried out in cases in which the infection is localized to the skin, while in cases of systemic blastomycosis the prognosis is nearly hopeless. Large doses of potassium iodide by mouth and roentgen rays locally are generally effective.

Fig. 4.—Monilia paronychia and onychia.

tive, while a small lesion may be excised successfully if the diagnosis is made early.

Chromoblastomycosis.—Chromoblastomycosis is a chronic infection of the skin caused by at least six species of fungus, the most common reported in the United States being *Phialophora verrucosa*. The disease was first recognized in Brazil in 1911 and in the United States in 1915.¹⁸ In recent years it has been reported with increasing frequency.¹⁹ Any exposed part may be affected, and the foot is often the site of the infection. There is generally a history of injury with wood, and the lesion appears at the site of injury within a few weeks. The lesions have been classified into five clinical types: the verrucous, the tuberculoid, the syphiloid, the psoriasiform and those which result in elephantiasis from scarring. They are generally unilateral; pain and itching are absent, and the course is chronic. The diagnosis is not ordinarily suggested clinically; in most cases it is made only on microscopic examination of the tissue. The microscopic appearance is that of chronic granuloma, with the characteristic fungus cells being found both free and within the giant

cells. Because of the multiplicity of the types of lesions seen, chromoblastomycosis must be differentiated clinically from nearly all the chronic granulomas and tumors, and a microscopic examination is always necessary. Surgical excision or destruction by electrocoagulation may be successful in eradicating small lesions. Large doses of potassium iodide and roentgen rays may at times be helpful.

CONCLUSIONS

In recent years fungous infections of the foot have become endemic throughout all parts of the United States. Much progress has been made in the direction of refining methods for the diagnosis of fungous infections and for combating these diseases both by local and by biologic measures. Rapid transportation and the worldwide movement of great masses of men will inevitably result in a wider distribution of fungous infections that have until now been limited to isolated sections. It is to be hoped that the increased mycologic research that will thus be stimulated will provide new weapons of defense against this menace.

COMMON HYPERKERATOTIC LESIONS OF THE FOOT

ROYAL M. MONTGOMERY, M.D.

AND

ANDREW H. MONTGOMERY, M.D.

NEW YORK

The high percentage of those who have been rejected or deferred because of foot defects among civilians called to the armed services bears out the often quoted saying that no part of the body is more neglected in general medical practice than the feet. A recent article led "Health of Selective Service Registrants"¹ states that 30,000 of a total of 720,000 examined were unqualified for general military service because of foot defects. Of these, 21,000 were qualified for limited military service and 9,000 were disqualified for any military service.

A large number of those qualified for limited service have defects that are remedial. Many of these defects could have been prevented by giving better attention to footgear in early childhood and youth. Frequent examinations will prevent many bony malformations which later lead to various keratotic lesions of the feet. These preventive measures are neglected now. Even the treatment of minor defects of the feet, regardless of the pain and the disability which they cause, has been neglected by the physician.

Common hyperkeratotic lesions of the feet are discussed here. Such conditions as keratosis blennorrhagica, arsenical keratoses, congenital keratosis palmaris et plantaris and climacteric hyperkeratosis occur so rarely that they are of interest only to the dermatologist. The common lesions with which the physician in general practice can do much are callus, clavus and verruca.

We have been fortunate in having had an exceptional opportunity to diagnose and treat an unusually large number of foot lesions. We do not wish to appear dogmatic but we have seen many mistakes in the diagnosis of keratotic lesions of the feet and errors

in the application of radiotherapy. The recognition of these simple lesions and their proper treatment would prevent many unfortunate sequelae.

CALLUS OR CALLOSITAS

Ordinary callus is a circumscribed or a diffuse hyperkeratotic or indurated area of the skin. The area may be covered with loosely adherent flaky corneous tissue masking the papillary lines. At times this horny mass may be $\frac{1}{4}$ inch (0.5 cm.) thick and very firm. When this is shaved off, the papillary lines are all clearly visible and are not interrupted or broken. There is no central core, and thus a callus is differentiated from a corn. A callus results almost invariably from unusual friction or pressure or both. On the foot it is due either to faulty footgear or some orthopedic condition, such as displacement of the head of one or more metatarsal bones. A callus may cause a burning sensation or definite pain.

Treatment.—Paring, shielding and wearing properly fitting shoes usually effect a cure. The callus is gradually thinned by shaving carefully with a sharp scalpel until the skin is of nearly normal thickness. Moleskin adhesive plaster is placed over the area. A thicker felt pad or a foam rubber one may be placed behind the callus to raise a depressed metatarsal head. Before shaving, applications of 40 per cent salicylate acid may be used to thin the callus.

Excision of a callus is not recommended, because a painful scar frequently results in its place. Roentgen therapy² is usually unnecessary and is inadequate unless the pressure is permanently removed. It is to be condemned in cases in which the plantar fat pad has been thinned.

When pressure results in central vascularization of the callus, roentgen rays are of value to relieve pain and desiccate the capillaries. The rays should be given to the central vascularized part only, in doses of 300 to 600 roentgens. We have found much damage from large doses of roentgen rays or radium given to large areas. The formation of an ulcer is the most common harmful result of overirradiation of a callus.

Cooperation with an orthopedist or a chiropodist is often advisable. A metatarsal bar properly placed behind the metatarsal heads may give pronounced relief in the case of callus.

CORN OR CLAVUS

A corn is a callus in the center of which is a conical horny mass. The base of this keratotic growth is directed outward, and the apex presses against the sensitive subjacent structures. The central core, or radix, is formed by compact laminated horn cells. It presses on and thins or destroys the subjacent epidermis until it reaches the underlying nerve endings, causing much pain.

Corns are termed hard or soft, depending on their location. Both types result from pressure on bony prominences. Hard corns extend over a bony prominence. Soft corns occur between the toes, where they become macerated by sweat.

The most common site for a hard corn is over the outer side of the small toe. A corn is sometimes found in a nail groove, on the tip of a small toe or on a pressure point on the sole of the foot. In the hard corn there is usually one core, but there may be several. Its shape depends on the contour of the bone beneath

This paper, in a symposium on "Cutaneous Disorders of the Foot," is published under the auspices of the Section on Dermatology and Syphilology.

and may be round, crescentic or ridged. Under the corn in many instances may be found a sac, a so-called adventitious bursa, formed by rupture of connective tissue, which eventually develops into a lined sac.

The soft corn is found most commonly in the interspace between the fourth and the fifth toe. It is usually in the most proximal portion of the toe web or on the medial side of the little toe and appears macerated. Frequently not until the macerated skin is pared away is the radix of the corn found. It may be single but is usually double and is located over two opposing bony prominences. Soft corns are extremely painful lesions. The soft corn has no connection with dermatophytosis. However, it has been mistaken for the maceration one often sees in that infection.

An ill fitting shoe may be a factor in producing a hard or a soft corn by causing intermittent pressure over some bone or joint. Palpation reveals a subjacent prominence. An improper shoe may also upset the mechanics and muscle balance of the foot. This may cause abnormal apposition of bony heads.³

Treatment.—The prevention of corns depends primarily on a change to footgear of the proper size and shape. Conservative therapy is preferred and consists mainly in paring and then protecting by shielding over bony prominences with felt, foam rubber or latex pads. This palliative measure gives the patient temporary relief. For permanent relief, Fripp and McConnel⁴ stress the restoration of proper muscle balance. They advise proper exercises for the feet, faradic foot baths, adhesive strapping to prevent spreading of the metatarsal bones and properly fitted shoes. Occasionally, radical excision of a hard corn and the adventitious bursa when present will effect a cure. At times the bony prominence underlying the corn will have to be removed. Operation for hammer toe, tenotomy or amputation of the fifth toe may have to be performed in some cases.

Roentgen therapy⁵ helps in the relief of pain. It stops the active production of the horny mass making up the corn. Roentgen rays are given to the lesion with close lead shielding in doses of 800, 650 and 500 roentgens at ten day intervals. In our experience, however, radiotherapy has never resulted in permanent benefit in the case of the common corn, hard or soft.

Injection therapy⁶ uses long acting local anesthetics. These are injected in a fan shaped area proximal to the corn. The corn may then be dissected out and a thin felt pad placed directly over the site. Injection alone relieves the pain and frequently effects a cure. Forty per cent salicylic acid plasters may be used with caution, but only on patients who are nondiabetic and who have normal vascular systems. If a hard corn is infected or shows a sinus, soothing wet dressings are indicated. At times a roentgenogram of the phalanx should be taken. The application of 95 per cent phenol or 50 per cent solution of silver nitrate to the sinus often aids in its closure. In the treatment of soft corns conservatism is best. Only in rare instances will it be found necessary to do surgical excision.

In most cases, with a change to more roomy footgear, further therapy comprises dissection of the radix of the corn with a special type of curved chisel, a "soft corn

spoon," elevation of the head of the fourth metatarsal bone by a foam rubber shield and local application of 50 per cent silver nitrate solution to the pared corn. Separation of the involved toes gives relief. This is done by inserting a small felt wedge shaped as a duck's bill, a piece of foam rubber or lamb's wool.

There may be two complications in the case of soft corn, either of them serious in the presence of diabetes or of a disease of the peripheral circulation. In addition to the usual pain of the corn itself there may be inflammation and swelling extending to the dorsum of the foot. Soft corns may be infected by self paring and careless use of advertised solvents. Drainage and wet dressings are indicated. A sinus may complicate the lesion. It may lead into a dilated sac, which should be opened, curetted and packed, or there may be a sinus extending to the flexor tendon sheath.⁷ In some instances a sinus yields to phenol applied to its depth on a fine applicator. In others complete excision of the sinus is required.

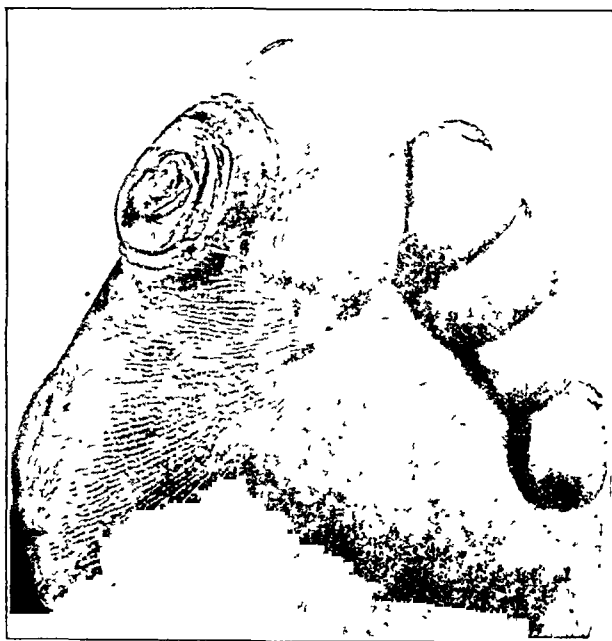

Fig 1—Corn on the big toe showing pronounced lamination of horny tissue

NEUROVASCULAR CORN

The neurovascular corn is rarely mentioned in medical literature but it has long been noted by chiropractors. It is a definite entity. It is usually located under the first or the fifth metatarsal head; at times it may be on the plantar aspect of the big toe or the dorsum of the fifth toe. It is vascularized and intensely painful. Hypertrophied blood vessels may be seen through the transparent horny layer, lying parallel with the surface and not vertically as in verruca. Close examination may reveal minute superficial fissures. After the corn has been shaved, threadlike nerve elements may be seen interspersed with the blood vessels. The corn is small, rarely larger than $\frac{3}{16}$ inch (0.5 cm.) in diameter. It occurs in the hyperthyroid person or in the person with thin textured, delicate skin.

Treatment.—Lesions of this type are resistant to all therapy. They have frequently been mistaken for warts and have been much irradiated without close shielding

both with roentgen rays and radium. These unfortunate mistakes have often led to chronic ulceration. Since the neurovascular corn is always under a bony head, excision is definitely contraindicated. The resulting scar usually is more painful than the original lesion. However, excision with plastic repair might give a successful result. The best treatment is a combination of roentgen therapy and application of local astringents and padding. When roentgen rays are to be given, the lesion is shaved down and its border outlined carefully in ink. Three doses are given at ten day intervals to this area alone. The initial dose is 800 roentgens, the second 650 roentgens and the third 500 roentgens unfiltered. Irradiation of the corn inhibits further development. Local applications of 50 or 100 per cent

Fig. 2—Mosaic wart with scattered outlying warty elements

silver nitrate solution are made after the roentgen therapy. These applications may also be made without roentgen therapy.

Following the sedative astringent effect of roentgen therapy, best results are obtained by shielding with foam rubber. A piece, preferably $\frac{5}{8}$ inch (0.8 cm.) thick, cut to the shape of the foot from the middle of the long arch to the bases of the toes, skived at the margin, can be placed against the sole inside the stocking. When properly placed it remains in a fixed position. Occasionally, if further localized shielding is necessary, a crescentic piece of thinned foam rubber may be cemented about the painful lesion. This shielding may need to be renewed every second month.

Acid therapy gives little relief, although salicylic acid has helped in some cases.

Injection therapy with long acting anesthetics,⁶ as mentioned with respect to hard corns, has given some relief.

WARTS, OR VERRUCAE

Warts, or verrucae, may be present on the feet. When on the sole they are termed verrucae plantares, and when on the dorsal surface of the foot or toes, verrucae vulgares or planae. Verruca vulgaris is the common seed wart which is so often present on the hands of children and adolescents. Since there is no pressure on the dorsal surface the warts are elevated. Plantar warts, which are nearly level with the surface of the skin, are divided into three types: the "single," the "mother-daughter," or "epidemic," and the mosaic warts.

Single warts are located under pressure points, usually under the metatarsal heads. They may be exceedingly painful. There may be two to four of these under the bony heads. Trauma acts as a definite etiologic factor. These warts are usually the same size. Each is surrounded by callus and has a sharply limited border. Paring reveals the border, and the capillary tips are seen. The tips near the border tend to spray out as if coming from a more central area at the base of the wart. Definite capillary bleeding may be present if paring is deep enough.

Warts of the "mother-daughter," or "epidemic," type may involve any part of the sole. There is a central larger lesion with outlying satellites, some of which may be so minute and transparent as to resemble vesicles. The original, or mother, lesion is usually surrounded or embedded in callus, while the smaller ones are not. At times an area of erythema surrounds them and they may be very painful. Shaved, the mother wart has the same appearance as the single type except that there is more definite radiation of capillaries. When the small vesicular lesions are pared, one or two capillary tips may be cut. Bleeding from these warty capillary tips is rather profuse and prolonged if not stopped by a styptic.

Warts of this type occur usually in adolescents under 18 years of age. They are often accompanied by warts on the hands.

The mosaic wart⁸ is a multiple patchy lesion limited almost invariably to the sole, though occasionally it is found in an interdigital area. To this type, one of us in 1928 applied the term "mosaic" to describe its surface characteristics. Warts of this type appear most commonly as patches of various size on pressure points of the sole, especially beneath metatarsal heads and the heel. They are irregularly bordered, dry and topped by a rather granular, friable, horny mass. They are usually painless.

Before paring, the skin appears rough and granular and the wart is often mistaken for and treated as a common callus. After paring, one sees an area composed of soft cornlike segments so closely packed that those in the central part have angular rather than rounded borders—hence the term mosaic. The individual cell or core is usually from 2 to 3 mm. in diameter. Patches may vary in size from that of a pea to 5 cm. or more across. Papillary lines on the sole are large and translucent, often transparent. By moistening the skin with alcohol, oil or glycerin one can see quite deeply. The earliest stage of a mosaic wart appears as a local widening of a normal papillary line. Sometimes two such minute growths appear side by side within a line. They increase in number and gradually form a patch. Numerous minute outlying patches may

⁸ Montgomery, A. H., and Montgomery, R. M.: Mosaic Wart: An Unusual Type of Plantar Wart, *New York State J. Med.* 37:1978 (Dec 1) 1937.

be found singly or in groups. Some superficially resemble common plantar warts but paring shows their multicellular character.

Coincident with plantar warts of any of these types there may be widely scattered warty lesions on the hands, the fingers or the dorsa of the feet. Accompanying mosaic warts these lesions are usually of the verruca plana type while with the other types they are of the verruca vulgaris type.

A verruca in a corn is another unusual type of wart. It rarely occurs. In a period of fifteen years we have observed about 30 cases. Patients usually complain of an unusually painful corn. Verruca of this type is generally located in a corn on the fifth toe, though it has been observed in a corn on the fourth toe or over a "bunion joint" and even in a soft corn. On paring the horny layer from the corn one can see a central core. When the skin is moistened with alcohol or with glycerin definite capillary tips diagnostic of a wart are seen. The border is sharply margined. Occasionally a wart of the mosaic type is found in a corn. In that case the border is irregular.

The infectious nature of warts has been proved by Wile and Kingery,⁹ Sulkin and Harford¹⁰ and others. They are caused by a filtrable virus. The presence of inclusion bodies in the cells has been established. Epidemics of the "mother-daughter" type occur in schools and institutions. Trauma from a stone or a nail frequently precedes the single type of wart.

Treatment.—The various means of treating verruca follow. The best therapy usually depends on the type present and whether it is radioresistant or radio-sensitive.

Surgical excision is an easy and efficient means of removing both the plantar wart of the "single type" and the "seed" wart. It should not be used for the

Fig. 3.—Wart in a corn. Note sharply margined warts with capillary tips in the center.

mosaic or the epidemic type. The ulceration caused is slow in healing on the plantar surface. Painful scars may result.

Electrosurgery is an excellent means of removing all but the mosaic type. The lesion may be curetted and

the base desiccated or coagulated. The disadvantages are the long period of disability due to ulceration and the possible postoperative painful scar.

Psychotherapy is successful with the epidemic type of wart. There are many forms.¹¹ Rubbing the warts with a piece of stolen meat is an old method. More recently bismuth salicylate, sterile saline solution and

Fig. 4.—Epidemic type of verruca plantaris cured by psychotherapy by insertion of a sterile needle in the buttock.

other solutions¹² injected intramuscularly have been used. Patients have been cured by inserting only a sterile intramuscular needle into the buttocks.

Injecting local sclerosing solutions¹³ directly into the base of the wart has proved successful. A small amount, 1 to 3 minims (0.06 to 0.18 cc.), is used. A larger amount will cause necrosis of the surrounding tissue. This type of therapy is best used for the single type. It is unsuccessful with mosaic warts.

Treatment of warts of all types with acids is successful. Chiropodists cure over 90 per cent by this means alone. Salicylate, nitric, trichloroacetic and dichloroacetic acids are the most popular. The caustics usually leave no scarring, although the treatment itself is painful.

For the mosaic wart, acid therapy has been most successful and is the treatment of choice. In our experience⁸ the most satisfactory method comprises the use of salicylic acid followed by silver nitrate. A 40 per cent salicylic acid plaster cut to the size and the shape of the wart is applied. It may be reenforced with 60 per cent salicylic acid ointment. Monochloroacetic acid may be swabbed lightly over the warts first. This treatment is repeated every five to seven days after the removal of the macerated tissue.

When the thin rete is exposed, it is swabbed with a strong silver nitrate solution (1 grain to 1 minim [0.06 Gm. to 0.06 cc.]) every five to seven days. Outlying patches and single lesions are treated similarly. Care is taken to protect the area from water between dressings. The patches heal usually without scar formation or damage to the plantar fat pad. The treatment outlined is somewhat painful. When monochloroacetic acid is used it may be necessary to relieve a serous

subwart reaction by incising the overlying tissue. At times wet dressings are necessary.

Radiotherapy: Radiotherapy consists in the use of either radium or roentgen rays. In many cases radiodermatitis and ulceration follow the application of radium to the sole. The aberrant rays invariably affect normal tissue, causing these harmful effects. For that reason we do not approve of its use for plantar warts. However, many skilled operators get good results.

Roentgen therapy is a safe and efficient means of treating the plantar warts which are radiosensitive. The results we reported in 1941¹⁴ showed a total of 90.35 per cent cured by this method alone. Briefly, it comprises the use of a predetermined large initial dose. This is followed at ten day intervals by one, two or three saturation doses, four fifths of the initial dose, through

Fig. 5.—Plantar radiodermatitis with ulceration. Note hyperkeratosis about ulcer and outlying telangiectasia.

a precisely fitting shield hole in lead sheeting. The hole is reduced in size as the lesion shrinks. There has been an entire absence of subwart reaction or of any other unfortunate sequela. It is effective, safe, painless and comparatively rapid and entails no disability. It is the preferred method for patients with diabetes and those with faulty peripheral circulation.

In summing up the treatment for warts occurring on the feet, electrodesiccation with curettage is preferred for verruca vulgaris or plana and for verruca in a corn; radiotherapy, for the single and the epidemic type, although psychotherapy should be tried first in many of the latter cases; a special acid therapy, for the mosaic warts.

PLANTAR RADIODERMATITIS

Radiodermatitis of the plantar surface of the foot presents a fairly characteristic picture. It results from excessive irradiation by means of roentgen rays or

radium. The radiation was given usually for neurovascular corns or mosaic warts, both of which are radio-resistant. At other times a large area was irradiated without close shielding.

The radiodermatitis usually occurs over a bony prominence. Irradiation frequently destroys the fat pad, thus causing the underlying bones to traumatize the skin. The involved area may vary in size from $\frac{1}{4}$ inch to 2 inches (0.5 to 5 cm.) in diameter. It is thickened and may be covered with considerable horny tissue. In one such area which we saw the horny tissue was $\frac{3}{4}$ inch (about 2 cm.) thick. These areas may or may not be ulcerated. When the keratotic material is shaved off, scarring is evident, with the loss of normal papillary lines. At times small horny nuclei are present in the scarred area. Capillary tips varying in size and perpendicular to the surface are seen. Often small warty areas may be found in the lesion or about the periphery showing that the original lesion was a mosaic wart, which is resistant to irradiation. Frequently typical telangiectasis and erythema are found surrounding the keratotic area.

Ulceration is often present in these keratotic lesions. The ulcers are usually small, simulating sinuses. They may be single or multiple and are usually $\frac{1}{8}$ inch (about 0.3 cm.), in diameter though they may be pea sized or larger. Sometimes they are linear. The base of the ulcer is a dirty gray. Ulcers due to irradiation are always difficult to cure.

Areas of plantar radiodermatitis in which there is hyperkeratosis are usually painful. When ulceration is present, pain is more intense. The fat pad may be thinned or destroyed in this type of radiodermatitis. When an extensive burn is present, the underlying bones become rigid, owing to scar tissue. Walking is usually difficult and painful. Pain may be present even when the foot is at rest.

Treatment.—Conservative treatment of radiodermatitis is best. Relief of pressure over the bony prominences is the most important factor in treatment. This is carried out by placing felt or foam rubber padding on the sole. The pad is placed posterior to the involved area and may surround it in a horseshoe manner to give relief. Foam rubber pads may be put directly over the involved area, cushioning it. Therapy is directed toward preventing ulcer formation by means of soothing or stimulating remedies and protective padding. Keratolytic ointments and plasters are contraindicated. Paring with a scalpel is the best method for removing keratotic tissue. Local therapy is of little avail in the scarred area. If ulceration is present, its healing is most important. Best results are obtained with an ointment containing cod liver oil, urea and tannic acid. To this ethyl aminobenzoate may be added. Aloe vera jelly has been recommended, but it is difficult to use when the patient is ambulatory. If this conservative therapy does not give proper results within several months, excision of the area with skin grafting may be carried out as recommended by Blair, Brown and Byars.¹⁵

Roentgen therapy is not condemned for certain hyperkeratotic lesions when given with the proper technic and dosage. Radium should not be used with lesions of the feet because there is lateral irradiation of the normal skin even though the lesions are well

14. Montgomery, A. H., and Montgomery, R. M.: Roentgen Ray Therapy of Plantar Warts, *New York State J. Med.* 41: 371 (Feb. 15) 1941.

15. Blair, V. P.; Brown, J. B., and Byars, L. T.: Plantar Warts, Flaps and Grafts, *J. A. M. A.* 108: 24 (Jan. 2) 1937.

shielded with lead. Unfortunately, when radium and roentgen rays are given in excessive doses and with faulty technic this destructive type of plantar radiodermatitis results.

DIFFERENTIAL DIAGNOSIS OF CALLUSES, CORNS AND WARTS

A roughened central mass in an encircling smoother callus should call for investigation. In differentiating lesions of this type one must shave the lesion down until a smooth surface is obtained. Moistening it with alcohol, oil or glycerin aids in the diagnosis. In callus the normal ridge and furrow system is maintained without any breaks in the papillary lines. The area is just thickened and hyperkeratotic. In a corn the calloused area is interrupted by a central horny core which contains no vascular elements. It is painful on direct pressure.

In the "single type" plantar wart the papillary lines are deviated around or interrupted by a small central mass. On superficial paring one finds an oval or rounded horny mass varying in color from the normal skin and sharply limited from it by a light, often transparent horny membrane. In the central mass can be seen minute dark points, which are coagulated blood in the tips of enlarged papillae. These capillaries seem to flare out from a more central point. Further paring opens these tips, causing capillary bleeding. Pain is elicited more by lateral pressure than by direct pressure. If multiple they are all about the same size.

In the epidemic type of plantar wart there is one large original wart similar to a "single type" wart. Surrounding this may be many small warts, at times as many as twenty-five or thirty. These may have a vesicular appearance and are painful. They occur in adolescents.

In the mosaic wart the character of the border of the patch is most diagnostic, and the wart cells are grouped in a mosaic pattern. The border is diffuse and not sharply margined. Small individual warts may be seen near the border of the larger patch. The capillaries in the warty core which come to the surface do not flare out as in the common type of plantar wart.

It is most important to differentiate the neurovascular corn from plantar warts and the hard corns occurring on the sole because of its resistance to most therapy. The neurovascular corn is intensely painful and is located beneath a prominent metatarsal head, usually the first or the fifth. Hypertrophied blood vessels may be seen through the transparent horny surface, lying parallel with the surface.

In plantar radiodermatitis there is a history of previous irradiation of the involved tissue. Scarring or ulceration is present. Various sized capillaries come to the surface of the horny area, which seems to be divided by the scarring into horny "islands" of various sizes and shapes.

SUMMARY

The common hyperkeratotic lesions of the feet include callus, hard, soft and neurovascular corns, warts and plantar radiodermatitis. Differentiation of these simple lesions and their proper treatment as outlined in this paper would prevent many unfortunate sequelae.

57 West Fifty-Seventh Street.

BENIGN AND MALIGNANT TUMORS OF THE FOOT

GEORGE V. KULCHAR, M.D.,
SAN FRANCISCO

The division of tumors into benign and malignant provides a convenient but not wholly accurate means of classification. Neoplasms which remain localized to the site of origin are regarded as benign, while those which invade the surrounding tissue and metastasize are termed malignant. Certain benign tumors, however, may at times assume the clinical and the histologic characteristics of malignant tumors and conversely some usually regarded as malignant may in their clinical course be essentially benign. Furthermore, if the differentiation is based on the histologic features, more particularly the increased capacity of the tumor cells for proliferation, some tumors—for example, basal cell epithelioma—while displaying all the microscopic characteristics of malignancy are relatively benign in their clinical behavior. So the clinician, and even at times the pathologist with the tissue actually before him, has difficulty in determining whether the neoplasm should be regarded as benign or malignant. These limitations and criterial inadequacies for neoplasms in general apply equally to tumors of the foot, particularly as to the differentiation in the strictest sense between benign and malignant new growths.

Tumors of the foot, like those of the hand, differ from neoplasms elsewhere, as Pack¹ and others have pointed out, in being frequently multiple. This multicentricity of origin is due to several factors. Many tumors are congenital in origin although they may not appear until later life, while others develop symmetrically because of predisposing causes or a metabolic disturbance as, for example, xanthoma. In regard to some, as Kaposi's idiopathic hemorrhagic sarcoma, the reason for the multicentric origin is not as yet understood, although the presence of constitutional factors is recognized. Except for this multicentric tendency, tumors of the foot have for the most part the clinical features of neoplasms in general. The frequent and repeated trauma that the foot is subjected to may produce pain in lesions ordinarily asymptomatic or, as in melanoma, provide the stimulus for or accelerate the rate of transformation of a comparatively benign or potentially malignant lesion to one actually malignant.

Sporadic lesions occurring singly or as a part of generalized sarcoidosis or of lymphoblastoma (lymphosarcoma, mycosis fungoides and the leukemias) may appear on the foot. Similarly metastasis from a neoplasm elsewhere is at times encountered. The periostitis, osteoperiostitis and osteitis of late syphilis, while not tumors in the strictest sense, may simulate tumors. Syphilitic osteomyelitis of the bones of the foot may extend to the subcutaneous tissues and lead to the appearance of gummatous lesions in the skin. The nodular and nodular-ulcerative lesions of late syphilis on the foot must be differentiated from true neoplasms. Likewise, tuberculosis originating primarily in the skin

or extending from infection of the small bones of the foot may assume the clinical appearance of new growths (fig. 1).

Most of the benign new growths appearing in the skin or in the subcutaneous tissues elsewhere are at times found on the foot. Fibromas, lipomas, neuromas, myomas, keloids, the lesions of Recklinghausen's disease, molluscum contagiosum, various types of nevi and sebaceous cysts, aside from the discomfort caused by pressure, present essentially the same problems of diagnosis and management as similar lesions elsewhere. In this review are included only those tumors which frequently are seen on the feet or which, because of their location, present special problems in diagnosis and treatment.

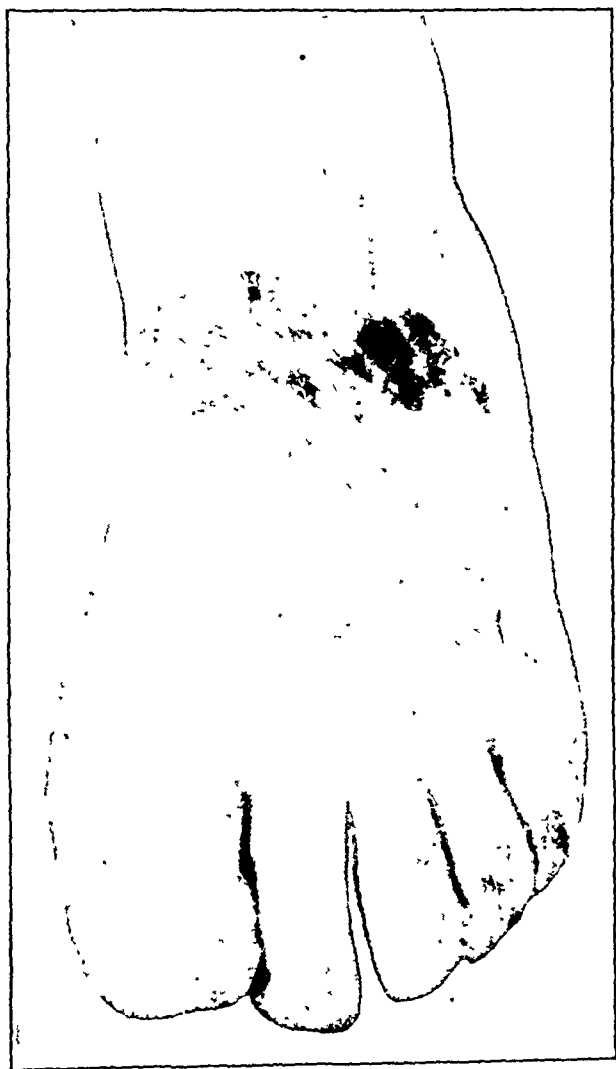

Fig. 1.—Late nodular ulcerative syphilid on the dorsum of the foot. The advancing indurated arciform border is on the left, on the right the pigmented atrophic scarring is seen.

FOREIGN BODY GRANULOMA

Granuloma resulting from penetration of the skin by a foreign body is common on the foot, usually occurring on the plantar surface. The initial lesion is a somewhat hyperkeratotic nodule. Growing slowly, the nodule may reach the diameter of several centimeters and cause some discomfort in walking. It may be destroyed by electrocoagulation or, if large, may be excised. On microscopic examination the tumor is made up of round and epithelioid cells interspersed with foreign body giant cells.

PYOGENIC GRANULOMA

Granuloma of the pyogenic type occurs frequently on the foot, the most common site being about the sulcus of a nail. The lesion is soft, vascular and sharply demarcated from the adjacent normal skin and may be

either pedunculated or sessile. Growth is usually rapid and may reach the diameter of a centimeter or more. Clinically the pyogenic granuloma simulates an infected angioma, although the differentiation is usually not difficult to make if one considers the history and the rapid development of the lesion. Small doses of x-rays or of radium usually cause rapid disappearance of the granuloma; if this therapy is not available, the tumor may be destroyed by electrodesiccation.

ANGIOMA

Various types of angiomatous tumors may appear on the foot. For some, as the glomus tumor, or angioneuroma, the foot is the most frequent site, while for others, as Kaposi's hemorrhagic sarcoma, it is frequently the site of the initial lesion. The great majority of angiomatous tumors are congenital in origin, and even in those appearing in later life the anlage has probably been present since early life. The many forms of angiomatous tumors, the difficulties of reconciling the histologic structure with the clinical course, the confusing nomenclature and the variable etiologic factors concerned, particularly as to tissue of origin, have contributed considerably to the difficulty of making a logical classification. The long existing confusion has recently been clarified somewhat by Oughterson and Tennant.² The difference in appearance, rate of growth and capacity to metastasize observed among angiomas of similar microscopic features becomes now, at least in part, understandable. Vascular tumors, according to Oughterson and Tennant, may be classified into three groups. The first group, the angiomas, includes the vascular malformations such as arteriovenous fistulas, the vascular nevi and the arterial, venous and lymphatic angiomas. Also included are the angioblastomas (hemangioblastoma and lymphangioblastoma), vascular tumors which are made up of rapidly proliferating cells and appear to be true neoplasms. The glomus tumors, or angioneuromas, comprise the second group, and the third is Kaposi's idiopathic multiple hemorrhagic sarcoma. The latter, despite the fact that its cause is unknown, is grouped among angiomatous tumors because of clinical and histologic similarities. Although they may be locally invasive and destructive and recur after attempts at removal, with the exception of Kaposi's sarcoma, the vast majority of the vascular tumors are not malignant in the sense that they metastasize generally or cause death. There have been, however, a few reports of metastasis from angioblastomas of the extremities (Ward and Jonas³).

Among the benign angiomas the most common are the vascular nevi. Frequently these are multiple, and usually they are present at or become evident soon after birth. Occasionally they may appear in later life and even in old age. The nevus, made up almost entirely of dilated blood vessels, may remain stationary or may grow at about the same rate as the body or at times with startling rapidity. With growth there may occur a displacement of the surrounding structures and at times even erosion of cartilage or bone. Benign angiomas may be in the skin, the subcutaneous tissues or the skeletal muscles or about the bones, the joints or the tendon sheaths. In the latter sites they may produce considerable pain and disability. In size they vary from a growth a few millimeters in diameter to a huge tumor involving the entire extremity. Either alone or in

combination with lymphangiectasis they may produce grotesque and gigantic enlargement of the foot or of the entire lower extremity (fig. 2).

The appearance of benign angioma is dependent largely on the site and the extent of the lesion. In the common port wine mark, or *nevus flammeus*, the vascular dilatations are small and more or less on the same plane in the skin, and the surface is smooth and flat, usually dark red. The most common vascular nevus, *hemangioma simplex*, is raised and even at times pedunculated, the surface is usually slightly irregular and the color varies from bright to dark red. *Cavernous angiomas* differ from simple hemangiomas in that the blood filled channels are connected with angiomatous vessels. They are frequently deep seated and large, and the color is dependent largely on the depth, so that at times they may be barely visible as a bluish tracery beneath the overlying skin. If more superficially located they vary in color from dark red to reddish blue. The skin may be atrophic and adherent.

Many angiomas involute spontaneously, usually over a period of years. Treatment if feasible should, however, be begun as soon as the tumor is discovered. There is no satisfactory method of treating the superficial, or *nevus flammeus*, type, although the water cooled quartz mercury vapor arc lamp applied with pressure may at times lessen the disfigurement. The simple and the cavernous angiomas are easily treated with x-rays or radium, given usually in small and well spaced doses, or by the injection of sclerosing substances. A lesion not responding to these measures may be surgically excised and, if necessary, the defect repaired by a skin graft. Small lesions may be destroyed with solidified carbon dioxide or by electrodesiccation. With proper and careful treatment the results are usually most satisfactory.

ANGIOBLASTOMA

Included in the angioblastoma group are the angio-blastic sarcomas, the angioendothelial sarcoma and the perithelial sarcomas. These tumors, despite their malignant clinical and histologic appearance, rarely metastasize, although they may be locally invasive and destructive. The tumor nodules are red or bluish red, vascular in appearance and frequently multiple. Larger lesions frequently ulcerate. The differentiation between the various tumors in this group is usually made by microscopic examination. If the lesion is small and readily accessible it may be excised, although irradiation, despite its limitations on the foot, is the simplest and usually an effective method of treatment.

ANGIONEUROMYOMA

Although first described many years ago angioneuromyoma, or the glomus tumor, has only recently received much recognition. In approximately one third of the cases it occurs on the lower extremity, the nail bed being the most frequent location. It originates from the neuromyoarterial glomus, is red or bluish red and small, seldom reaching a diameter of more than 1 or 2 cm. Growth is slow and not locally invasive. When the tumor is located beneath the nail the characteristic pulsating changes in color are less evident. While pain at times may be absent the glomus tumor is usually extremely painful, the pain being frequently paroxysmal and radiating in character, often initiated or aggravated by changes in the weather. The glomus tumor may be excised or destroyed by electrocoagula-

tion. Microscopic examination reveals a well encapsulated lesion made up of muscle, nerve and vascular tissue (fig. 3).

KAPOSI'S SARCOMA

Kaposi's idiopathic multiple hemorrhagic sarcoma occurs for some unexplained reason preponderantly among males of the laboring class native of northern Italy, Russia and Poland. The cause, like the reason for the geographic distribution, is not known, although trauma is believed by some to be one of the factors. After much careful study Dörffel⁴ concluded that the disease is primarily one of the reticuloendothelial system. The initial lesion, usually a small papule or nodule, is frequently on the leg or the foot. In the beginning the tumors are soft and vascular, but as they enlarge and coalesce to form red, reddish brown or bluish black plaques the tumor masses become firm

Fig 2—Enlargement of the lower extremity, including the foot, as a result of cavernous angiomas

and often hyperkeratotic. Frequently the lesions are symmetrical and bilateral. They grow slowly and after a variable time spread over the skin and involve the viscera, particularly the lungs and the lymph glands. Hemorrhages from the lesions in the skin and the viscera frequently occur. Edema of the leg or the foot and elephantiasis-like changes may ensue. The rate of progression is slow and variable, and spontaneous remission and regression of the lesions may at times take place, leaving pigmented atrophic scars. The duration of life is on the average between five and ten years, death being due to intercurrent infection, cachexia, visceral involvement or repeated hemorrhages.

Irradiation may occasionally be followed by a seemingly permanent regression, but in most instances there are recurrences. Small doses of about 75 roentgens

⁴ Dörffel, Julius: Histogenesis of Multiple Idiopathic Hemorrhagic Sarcoma of Kaposi, *Arch. Dermat. & Syph.* 26: 693 (Oct.) 1932

given at weekly intervals to the involved regions usually are effective, although for the more deeply infiltrated lesions larger amounts of filtered x-rays may be required. Arsenic in the form of solution of potassium arsenite or the intramuscular injection of solution of sodium arsenate is occasionally effective and should be used as an adjuvant to irradiation.

SYNOVIAL CYST

Originating from the synovial membranes of joints, tendon sheaths and bursas, cystic tumors are not uncommon on the foot. The most frequent sites are over the metatarsal-phalangeal articulations. The lesions are small, either nodular or globoid and at times hyperkeratotic over the surface. Usually they are painless, although at times they may cause some

Fig. 3.—Angioneuroma, or glomus tumor, beneath the nail of the great toe (patient of Dr. L. R. Chandler).

discomfort. When punctured they exude a syrupy fluid. These cysts may be surgically excised, although recurrences are frequent. Irradiation is at times effective in causing them to disappear.

GANGLION

The ganglion, common on the foot, results from fibroplasia and colloid degeneration of a synovial membrane, a tendon sheath or occasionally a tendon. It is smooth, rounded, firm, frequently multiloculated and on palpation gives the impression of containing gelatinous fluid. Aspiration of the viscid fluid followed by injection of a sclerosing substance is a simple method of treatment. If this is ineffective the ganglion may be excised.

FIBROMA

On the foot fibroma may occur as an isolated lesion or as a part of generalized fibromatosis (Recklinghausen's disease). Occasionally it is found in close

association with a tendon sheath or a joint capsule, but most commonly it is in the skin or the subcutaneous tissues. Fibromas vary in consistency from soft to hard and may reach a diameter of several centimeters or more. A variety of fibroma, histiocytoma cutis, which occurs most frequently on the extremities, has been described by Seneor and Caro.⁵ It is usually single, small, ovoid or round and either grayish brown or bluish red. Microscopic section shows this tumor to be made up of fibrous blood vessels, bundles and histiocytes filled with lipoid droplets and colloidal iron. Should treatment of a fibroma be necessary it may be destroyed by electrocoagulation, if small, or excised.

XANTHOMA

Tumors made up of lipoid containing histiocytes and fibrous tissue and resulting from a disturbance of the fat metabolism may appear on the foot, particularly on the plantar surface, as a part of disseminated xanthomatosis, as isolated lesions of xanthoma tuberosum multiplex or as large tumors involving tendon sheaths and joint capsules. Xanthoma on the skin appears as yellow-pink nodules varying from a few millimeters to one or more centimeters in diameter. Involution may follow and recurrences may be prevented by rigid restriction of fats in the diet.

The relation between xanthoma occurring as an isolated tumor in or about a tendon or its sheath or a joint capsule and the so-called giant cell tumor, or sarcoma, of these structures has been debated. The association of the latter tumor with xanthomas elsewhere, the frequent accompanying hypercholesteremia and the histiologic resemblances to xanthoma, including the presence of lipoid containing "foam cells," has led to the belief that the giant cell tumor is xanthomatous. On the feet the tumors appear commonly near the tendinous insertions as slow growing, usually painless, moderately soft or firm nodular masses. They may at times be attached to the capsule of the ankle joint. Destruction and invasion of the contiguous bony structures may occur, but the tumors are otherwise benign in their clinical course. Surgical extirpation is usually not difficult, although there may be recurrences.

MELANOMA

The capacity to produce pigment characterizes melanomas, although at times this is not exercised and the lesions are nonpigmented. In the strictest sense the term melanoma should be reserved for the highly malignant tumors originating in either the ectodermal or the mesodermal nevi. Lentigenes and pigmented and nonpigmented nevi, being ectodermal in origin, are the lesions from which melanocarcinoma originates, while the rarer mesodermal blue nevus is the precursor of melanosarcoma.

Approximately 15 per cent of all melanomas, according to Pack and Adair,⁶ occur on the foot, and of these slightly more than 8 per cent are subungual. For some not as yet understood reason the incidence among Negroes is comparatively lower, and interestingly, when melanomas are present the sole of the foot, where pigmentation is least, is the most frequent site. The relation of melanoma and trauma to presumably benign nevi has been much discussed. While the history of injury to, or the attempt at removal of,

5. Seneor, F. E., and Caro, M. R.: *Histiocytoma Cutis*, Arch. Dermat. & Syph. 33: 209 (Feb.) 1936.
6. Pack, G. T., and Adair, F. E.: *Subungual Melanoma*, Surgery 5: 47 (Jan.) 1939.

clinically benign nevi is often given, it may well be argued that the lesion was already malignant when the trauma occurred. Regardless of this controversy, in view of the high incidence of melanoma on the foot pigmented nevi should at least be carefully watched and if located in an area where friction and trauma are continual should for safety be excised, particularly if it is deeply pigmented or shows any evidence of growth.

In addition to increased pigmentation and growth the earliest signs of malignancy are an erythematous areola, a diffusion of pigment into the surrounding normal skin and a development of satellite nodules about the periphery. The rate of growth may at times be amazingly rapid until the tumor becomes a nodular mass with a broad or pedunculated base. The peripheral lesions likewise enlarge, and the individual tumor may reach the size of an orange; the surface frequently becomes ulcerated and covered with serous or purulent exudate. Metastasis to the regional lymph glands, to the internal viscera, particularly the liver and the lungs, and to the skin elsewhere is usually relatively early. At times diffuse melanotic pigmentation of the skin is the first evidence of generalization. Both the primary tumor and the metastatic lesions may occasionally be nonpigmented, in which event the diagnosis is made by microscopic examination (fig. 4).

The most common site of melanoma of the nail bed is the great toe. Because of the resemblance, this tumor was called "melanotic whitlow" by the older writers. Through the nail plate the pigmentation is at times difficult to make out. In the diagnosis of the lesions in an early stage the presence of the peripheral pigmentation is an important point. As the melanoma grows the nail plate is elevated and becomes thickened and fragile and eventually is destroyed to reveal a black, well demarcated fungating or ulcerating tumor.

The successful management of melanoma depends largely on early diagnosis and adequate removal. Suspected lesions should not be destroyed by cauterization with acids or the electrocautery but excised with a fair margin of normal skin for microscopic examination. Although some melanomas may be sensitive, irradiation should be used only as palliative therapy for advanced, inoperable lesions. The subungual tumor is best treated by amputation of the digit. A primary tumor elsewhere on the foot requires a radical excision carried down to the fascia, the cosmetic results being secondary to the thoroughness with which removal is carried out. When the diagnosis has been confirmed by examination of the tissue, a radical dissection of the regional lymph glands, whether enlarged or not, should be made either at the time of operation or very soon thereafter. While the prognosis is always unfavorable and a recurrence may suddenly appear after many years, the number of satisfactory results even in patients with regional metastasis is sufficient to warrant the attempt at a cure despite the extent of the surgical procedure.

CARCINOMA

On the foot primary carcinoma is relatively uncommon. It may originate from normal skin or from the scar of a burn, a discharging sinus, a keratosis or other benign lesion. Injury to the skin by mechanical friction or by irradiation may be a predisposing cause. Despite the frequency with which corns and calluses are found on the foot, carcinoma rarely originates from

these, as Mason⁷ and others have pointed out, indicating that repeated chronic irritation must be a minor factor. Likewise, for some unexplained reason, carcinoma seldom develops in chronic varicose ulcers (Tenopyr and Silverman⁸). While occasionally transitional or basosquamous cell carcinoma may be found, by far the most common is the squamous cell variety, usually of a relatively low grade of malignancy (group 1 or 2, Broders).

The early lesion is usually a firm indurated nodule with a scaly dry, almost parchment-like surface; at times it may be hypertrophic with a verrucous surface over which dilated capillaries traverse. Growth is usually slow, and ulceration may not appear for several or more years. Eventually, if untreated, the cancer becomes a large malodorous ulcer or a fungating mass,

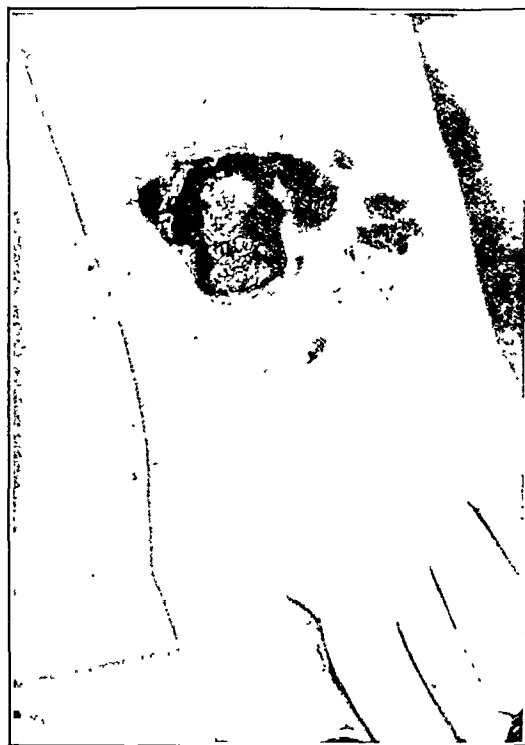

Fig. 4.—Melanoma on the dorsum of the foot. About the periphery of the large primary tumor are smaller pigmented satellite lesions.

frequently secondarily infected and extending to invade the underlying tendons, muscles and even bones. The regional lymph glands become enlarged, usually after several years or more, although this may be due to secondary infection and not necessarily indicative of metastasis. Metastatic lesions appear in the viscera, particularly in the liver and the lungs, and in the skin. For diagnosis and as a guide in therapy a biopsy should be made even though the clinical appearance may be so typical as to make it seem superfluous.

Except for small lesions and the rarer, more sensitive group 3 and 4 cancers, excision is to be preferred to irradiation in the treatment of carcinoma of the foot. Most of the lesions are relatively resistant, requiring large and destructive amounts of radiation. This, when given to regions where impairment of arterial and

7. Mason, M. L.: Carcinoma of the Hands and Feet, *Surgery* 5: 27 (Jan.) 1939.

8. Tenopyr, Joseph, and Silverman, Irving: Relation of Chronic Varicose Ulcer to Epithelioma of the Skin, Based on Records of Over 1,000 Chronic Leg Ulcers, *Ann. Surg.* 95: 754 (May) 1932.

venous circulation is common, particularly in the age group in which cancer usually occurs, frequently results in ulceration and necrosis with prolonged healing. Surgical excision with either primary closure or repair of the defect by an intermediate thickness graft is usually the preferred method of treatment. For the larger invasive and fungating cancer the removal of which results in extensive mutilating defects, amputation is at most times advisable. Carcinoma of a toe is usually best treated by amputation of the digit.

Frequently it is difficult to decide whether a radical dissection of the regional lymph glands should be made. Secondary infection in the tumor may be responsible for the enlargement and may simulate metastasis. Invasion of the lymph glands in the absence of palpable enlargement is rare, according to Mason. If palpable lymph glands are present a radical dissection should be done, as 50 per cent of the enlargements will be due to metastasis.⁷ Similarly a prophylactic dissection should be made when the primary lesion is deep and invasive or is so extensive as to necessitate amputation.

SARCOMA

Sarcoma is relatively uncommon on the foot. It may originate in connective tissue, muscle, nerve, tendon, tendon sheath or synovial membrane. From these, various types of sarcoma including fibrosarcoma, liposarcoma, myosarcoma, fibroneurosarcoma and synoviosarcoma are derived. The most common is fibrosarcoma, which appears first as a small, well circumscribed nodule that grows slowly to become a reddish nodular tumor. Ulceration is uncommon and, though the tumor is locally destructive and invasive, metastasis seldom occurs. Occasionally fibrosarcoma may assume the histologic characteristics and the clinical course of the highly malignant tumors. Dermatofibrosarcoma protuberans is a variety of sarcoma which may occur on the foot. Beginning as a small, flat, firm cutaneous or subcutaneous nodule it gradually enlarges to become a large blue or brownish sessile or pedunculated tumor. Although the tumor mass may reach considerable size, ulceration and metastasis rarely occur. At times regression and even involution may take place spontaneously.

Several types of sarcoma may originate in synovial membranes, tendon sheaths and tendons. The tumors usually manifest themselves as either slow or rapidly growing painful enlargements beneath the skin. Frequently there is a history of single or repeated trauma. In this group are included synoviosarcoma, arising from the synovial membrane, spindle cell sarcoma of the tendon sheath and joint capsule, whose origin may be difficult to determine, and sarcoma of the plantar fascia.

The diagnosis and differentiation between the various types of sarcoma are made largely by microscopic examination of the tissue. With the exception of lymphosarcoma, most of the neoplasms in this group are notably insensitive to irradiation. At times, however, irradiation is used in conjunction with the surgical removal of a deeply invasive tumor. The less malignant and early lesions may be radically excised and carefully followed for evidence of recurrence. Extensive and rapidly growing tumors, even in the absence of regional and pulmonary metastasis as well as recurrence, necessitate amputation, the resection being usually made at the junction of the upper with the lower two thirds of the leg.

In the management of sarcoma of the foot the fundamental principles that underlie the treatment of neoplasms in general should be followed. These are adequate diagnosis, which in most instances includes microscopic examination of the tissue, adequate treatment and adequate follow-up over a period of years.
450 Sutter Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. MADDEN, NOMLAND, CARO, R. M.
AND A. H. MONTGOMERY, AND KULCHAR

DR. R. C. JAMIESON, Detroit: The difficulty in diagnosing foot lesions which has been mentioned by Dr. Madden cannot be too strongly emphasized, as all lesions on the feet are "athlete's foot" to the layman. Consequently many proprietary preparations acquire an unjustified reputation for being a "cure" for fungous infections which were never properly nor correctly diagnosed. Many cases of dermatitis of the feet are aggravated or initiated by the use of woolen socks as well as by continued use of oil and water soaked shoes and to these can be added the use of home remedies, especially some of those publicized in lay magazines, which are potentially dangerous. Patients should always be warned to sterilize shoes with formaldehyde vapor and not put the liquid in the shoes. Contact dermatitis is not usually seen by the dermatologist until after the use of many fungicidal remedies, and it is then difficult to determine the origin; but the location of the original dermatitis should give the clue as to whether it is of fungous origin or not. The problem of psoriasis of the feet is interesting and usually difficult, especially when the nails are involved and there are no lesions elsewhere on the body. Psoriatic nails are usually dismissed or treated as fungous infections, and the tendency is to overtreat no matter what method is used. Excessive roentgen therapy is too often used, but on the feet it should be used even more cautiously than elsewhere. I am rather pessimistic about the ease of cure of neurodermatitis of the feet, as many resist everything—x-ray and local treatment of all forms. The greatest caution should be used in the treatment of plantar warts by roentgen rays. Many such warts require far more treatment than is safe to give and in a few cases malignant growths have resulted. In my judgment now it is wiser to use remedies not so potentially dangerous.

DR. PAUL A. O'LEARY, Rochester, Minn.: Although thromboangiitis obliterans is not observed exclusively among cigaret smokers, it is nevertheless advisable to have patients suffering from this disease discontinue smoking entirely. Occasionally in mild types of cases the elimination of cigarets will modify the symptoms considerably, and the few women I have seen who had thromboangiitis have been heavy smokers. The influence of the ill effect of the cigaret paper rather than the tobacco has led to suggestive but not conclusive deductions. The arctic explorers and northern woodsmen have long known that, when their hands or feet were badly nipped by the cold, if they rubbed the affected extremities gently with snow but not with ice they had less pain than if they did not do this. The temperature of snow is not as low as that of ice, and the gentle rubbing and massage, which must not be vigorous, are of help. When blisters appear a day or more after exposure, the treatment is similar to that of a second or third degree burn by the use of boric acid ointment, sterile dressings, rest, elevation and so forth. The application of cool wet dressings is more comfortable than that of heat, especially when secondary infection occurs. Livedo reticularis is a fairly common disease. It is characterized by blotchy and reticulated blueness of the extremities and is seen most often among young women. It is associated with varying degrees of dyshidrosis and can be distinguished from the occlusive vascular diseases by the absence of occlusion of the vessels. The network of lividity usually found between the ankles and the knees is characteristic. Exposure to cold aggravates the condition, as do emotional upsets. Recently Barker, Hines, Craig and others have reported successful results following sympathectomy in cases in which ulcerations of the legs and feet had developed. The mild types

of livedo reticularis are common and usually can be controlled by avoidance of undue exposure to cold; no medication has been helpful, as the cause of the disease is unknown. My observation of patients suffering from the combination of sclerodactylia and Raynaud's disease to which the term acrosclerosis has been applied has led me to believe that it is an entity allied to Raynaud's disease in contradistinction to scleroderma but quite distinctive from the former in a number of ways. Sympathectomy has been of help in these cases for short periods only, that is, one or two years. In many cases the disease is arrested spontaneously, resulting in atrophy of the subcutaneous tissues rather than of the skin. The arrest usually is accompanied by a considerable decrease of the vasospastic phenomena. In the severe forms of acrosclerosis, extensive gangrene resulting in spontaneous amputations of the digits has not been controlled by any of the measures used in overcoming spastic diseases of the blood vessels or sclerodermatous infiltrations. To say that these patients have scleroderma associated with Raynaud's disease is getting the cart before the horse, because the fundamental process appears to be in the blood vessels, not in the skin, and the degree of cutaneous sclerosis, although it is what the patient complains of, is of secondary significance.

DR. GEORGE C. ANDREWS, New York: I regret that the roentgen technic employed by the Montgomerys is not given in greater detail. Mention of the roentgen unit technic alone without giving the voltage and filtration is incomplete. In my opinion the so-called mosaic wart is an advanced type of growth in which multiple warts have coalesced into a patch. It is natural that this type is more difficult to treat than single and smaller lesions. Some mosaic warts occur on the convex aspects of the heels, so that equable distribution of dosage is not easy. However, I have cured too many of them by x-ray treatment or by a combination of electrodesiccation and intramuscular injections of bismuth to give up these methods. If acid treatment is to be used, I prefer to remove the mosaic wart by desiccation and to apply the acid to the base if any spots cause one to suspect a recurrence. This method shortens the treatment and, in my experience, is less painful than the treatment by acid alone. As to the etiology of corns and their tendency to localize on the outer side of the small toe, I would like to suggest another cause in addition to those mentioned by the authors. If one will examine the inside of almost any stocking or sock, one will find a piece of redundant thread at the outer end of the seam. This thread is often $\frac{1}{2}$ to 1 inch in length. It has a tendency to become wound into a hard little ball which rests on the outer surface of the small toe, into which it is pressed by the shoe. I suspect that many corns are caused in this manner. Squamous cell epithelioma of the foot is extremely rare. I have seen 2 cases in ichthyosis hystrix (horny epidermal nevus). Arsenical epitheliomas occur more often in the hands than on the feet. I am glad that Dr. Kulchar emphasizes the fact that hemangioendotheliomas, despite their histologic features that may suggest a type of sarcoma, are really not malignant and, if thoroughly removed, do not recur.

Hospital Room Construction.—In parts of the United States where hospital planning is regulated by local legislation the minimum cubic space allowance for patients in public wards is only 800 cubic feet. With the existing tendency to the use of low ceilings, say 10 feet in height, an allowance of 800 cubic feet per patient corresponds to 80 square feet of floor space per bed. American authors usually propose the more liberal standard of 1,000 cubic feet. A private room based on the minimum requirement of 800 cubic feet would measure only 8 by 10 feet, but rooms so diminutive are extremely rare. Rooms 9 feet 6 inches by 13 feet, 10 by 14 feet, 10 by 15 feet and 11 by 16 feet are more common. De luxe rooms are, of course, larger. These measurements do not include the private or individual toilets or baths that are nowadays so widely used, not so much for the patient's comfort as to facilitate nursing service.—The Hospital in Modern Society, edited by Arthur C. Bachmeyer and Gerhard Hartman, New York, Commonwealth Fund, 1943.

THE CONCEPT OF ORGANIC UNITY AND: PSYCHOSOMATIC MEDICINE

GEORGE DRAPER, M.D.

NEW YORK

From earliest times, physicians have been embarrassed by what seemed to be two separate phases of man. One of these, ponderable and physically tangible, has been called the body or soma; the other, termed psyche, imponderable and invisible, likewise appears as an immensely powerful factor in his being.¹ What the relationship of these two aspects of the creature might be, and how they may interact, has been a point of controversy throughout the history of medicine. One thing about them, however, has been definite: They are both, in some way, included in the individual animal unit. The term "psychosomatic medicine" was coined with the intent of bringing the parts together. Unfortunately, the two-pronged word does not adequately succeed in establishing the connotation of biologic unity. It still implies that the two parts, each with complete independence, work reciprocally on each other. This belief does not satisfy sound biologic tenets, and it tends to oversimplify the science and art of clinical medicine.

The infinite complexity of any living organism is a challenge to man's usual habit of finite thinking. Therefore, in the attempt to understand even a one-celled animal, it has been divided into the cytoplasm and nucleus. But when we strive to reassemble the creature so that it functions properly again, we still find ourselves in the frustrated company with all the king's horses and all the king's men. Moreover, when through special interest the focus of an investigator's individual attention becomes fixed on a part, the latter grows for him in significance until it often attains the power of a dominant minority. And beyond these considerations we are faced with the age-old problem of the relative significance to human beings of the terms mind and matter. Where does the physical body end and consciousness begin? Or does the latter exist free in the cosmos and pounce demon-like or godlike into the prefabricated animal carcass? It is not my purpose in this essay to carry on that discussion. But it is necessary to point out that the only way in which man has been able to deal with the imponderable forces which he has sensed to be present, either within or about him, is by abstract words or symbols. There is, however, a peril in this process, the danger that the possible, wished for or probable reality for which a given abstraction stands may be obscured by the poignant connotation of the symbol itself, which then takes on the fixed nature of a reality. This widespread insensitiveness to, or misinterpretation of, symbolic impact has perhaps been one of the great obstacles to a prompter, wider acceptance of any threat to traditional standard beliefs. Furthermore, in the very term "psychosomatic" the same danger still lurks about the first half of the Janus-faced word. Even the hybrid contraction "psysomatic"² is unhappy, coined as it was in order to connote, at least by the elimination of one syllable, a more intimate relationship between mind and body. And so, as studies in human constitution

From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

1. Some of the material in this article is also presented, but often differently phrased, in the book entitled *Human Constitution in Clinical Medicine* by the same author and published by Paul B. Hoeber, Inc., the Medical Department of Harper and Brothers, New York, 1944.

2. Draper, G.: *Disease—A Psychosomatic Reaction*, J. A. M. A., 90:1281 (April 21) 1928.

have proceeded,³ increasing dissatisfaction has developed with the term psychosomatic. By virtue of its structure it still implies a dichotomy, criticism of which was earlier implicit in Jelliffe's⁴ phrase "psychosomatic monism." Consequently, until a chemical and physical formulation is achieved which will explain the two expressions of energy which are now called reason and emotion on the one hand and somatic physical phenomena on the other, we are inevitably constrained to use abstractions for things sensed but imponderable and unknown. We shall have to accept frankly the statement of William James that "All our abstracts must be confessed to be but imperfectly imaginable things."

It is because of the foregoing difficulties and dangers that somatologists and psychologists together have recently been passing through what might be called "jamming" operations. The significance of that figure will at once be apparent to any one who has observed the capillary blood flow in a frog's foot. There one sees the individual corpuscles being tumbled along by the inexorable current, all hurtling in the same direction. They stumble, one after the other, sometimes in single file, some rudely passing others or establishing an impasse at forks in the tubing. But such controversies usually arise from misunderstanding of the meaning of meaning.⁵ Actually, psychiatrists and internists alike are pursuing the same objective, namely the nature of the man within the patient. Perhaps recourse to the natural historian's point of view may be of value in clearing the air.

THREE CONCEPTS

In the early part of this century a group of observers, including such men as E. B. Wilson, F. R. Lillie, Jacques Loeb, F. E. Ritter, T. H. Morgan, C. M. Child, E. G. Conklin and R. G. Harrison, broke away from what had been called the elementalist school and, following Aristotle, considered the living creature to be greater than its parts and sought to examine the organism as a whole. There were three essential concepts which emerged from this philosophical discipline. The first of these was well stated by Child.⁶ "Each living thing," he wrote, "represents an order and unity of some sort, maintaining itself with more or less success in a changing environment." For the second Ritter⁷ then insisted that the material substratum of life is not a single chemical individual or substance, protoplasm, but actually many protoplasms. Differing qualities of these protoplasms are inherent in the cells and therefore must represent genetic biologic substrates which inevitably determine first the differences between species, then, more subtly, those between individuals of the same species, and finally those between all organs and tissues within the individual. This notion is supported by the experiments of H. V. Wilson,⁸ which demonstrated the failure of fusions between mixed cells of different species. And the principle is further illustrated by Leo Loeb⁹ and by Morgan¹⁰ in their studies on grafting and fertilization, which have shown that

"the results are more successful for unions between closely 'related' forms than between distantly 'related' forms." Furthermore, it is well known to surgeons that homologous grafts are essential to the surest success. Leo Loeb regularly uses the phrase "individuality differential" as determined by the varying behavior of autotransplants, homoiotransplants and heterotransplants. Indeed, he speaks of transplantation as "an instrument for the analysis of individuality."

The third concept, that concerned with internal environment, may be divided into two parts, the humoral and the cellular. The former, probably first demonstrated by Claude Bernard in 1859, has recently been brought strikingly to mind again by Cannon's¹¹ emphasis on the circulating fluid elements of the body. This inner fluid environment is remarkable for its stability. Moreover, it serves to ensure by fluid bonds E. B. Wilson's¹² tenet that the real unity is that of the entire organism. "As long," he writes, "as its cells remain in continuity, they are to be regarded, not as morphological individuals, but as specialized centers of action into which the living body resolves itself and by means of which the physiological division of labor is accomplished."

The second part, that which deals with the reciprocal effects of neighboring cells and tissues on one another, has been fully reviewed by Ross G. Harrison.¹³ Moreover, these effects appear to be subject to orderly processes within the cell. For, as Conklin¹⁴ says, "There is something in the organization of the individual which makes it more than just the sum of its parts." And the presence of these orderly and specific processes within the cell can be explained only by genetic transmission.

Thus, for example, when the egg of a frog is turned, there is manifest rearrangement of its constituents. The cortical layer which holds most of the pigment and chief part of the gray crescent remain in position. But the main mass of the heavy white yoke rotates as a unit. In other words, turning the egg does not result in an indiscriminate mixing of the elements but in an orderly rearrangement which may result in a normal embryo. When the egg is inverted, at the two cell stage, the rearrangement takes place independently in the two cells, and twins may develop. Consequently, it appears that even in its earliest period development is affected by the interaction of cell constituents according to an orderly topographic arrangement.

ORGANISMIC POINT OF VIEW

The notion of specialized centers of action advanced by Wilson as an interpretation of the cell is reflected in the discoveries of Vogt,¹⁵ of Spemann¹⁶ and of Coghill.¹⁷ Vogt showed by means of appropriately applied dyestuffs that early amphibian embryos are composed of a mosaic of discrete cell masses and that each one of these cell blocks goes on to the formation of a specific adult part or system. The predestination

of each block apparently is constant, so that the presumption seems justified that this segment of the embryo will develop, for example, into liver, that into heart and another into central nervous system. But then Spemann found that if presumptive abdominal skin from one gastrula was transplanted into the region of the future medullary plate of another the transplanted skin developed into some part of the central nervous system. It is as though the gastrula receiving the transplant forced the transplanted cells into subservience and conformity with the needs of the complete host organism. Still more impressive support for the organismic point of view is found in Coghill's studies of the behavior of *Amblystoma* embryos. He traces the development of body movements from the nonmotile to the adult stage in relation to the growth of the central nervous system. At one point in his argument the following passage occurs: "In like manner, the tissues of the tongue receive branches from motor neurons that are engaged in integrating the trunk long before the tongue has muscle tissue in it. It is, therefore, the potentiality of the functional neuron to grow in embryonic fashion that gives to the organism as a whole its ability to subjugate new parts and thereby maintain its unity during the development of behavior. Such growth of the already conducting neurons accomplishes, then, the primary function of the nervous system, the maintenance of the integrity of the individual while the behavior pattern expands." Jelliffe⁴ has nowhere better displayed his grasp of the forces of growth and development in relation to constitution and the purpose of life than in the following sentence. Discussing Tilney's work on the development of the central nervous system, Jelliffe writes ". . . all of which shows how from the earliest forms the organism grew in response to future opportunities."⁴

Implicit in such observations of growth plan and pattern is the notion concerning body image suggested by Schilder¹⁸ and recently supported by Bruch¹⁹ and by Coghill¹⁷ himself. These authors concur in the belief that our bodies—indeed our whole personalities—have grown into images to ourselves of what we believe ourselves to be. "This image is built up in ourselves," writes Schilder, "in accordance with our instinctive attitudes;" while Coghill, the embryologist, considers man as "a mechanism which, within the limitations of life, sensitivity and growth, is creating and operating himself." Moreover, as Bruch points out, obese children, whose clinical problem is one of disturbed nutrition, "derive security satisfaction from the static fact of size alone." My own observations on total personality show that, in their morphology and behavior, peptic ulcer patients, also food problems in a way, are the very opposite of the obese. The ulcer bearer's best hope lies in hard effort, however useless or misdirected, to recapture that security which he first knew in infancy.³

Another interesting illustration of the principle of organismic unity drawn from the fields of immunity and pathology is seen in the recent observations of O. H. Robertson²⁰ on the behavior of pulmonary alveolar epithelium during pneumonia. These cells in health perform the highly specialized function of aiding in the exchange of gases between air and blood. During pneumonia Robertson observed that they take on a vigorous phagocytic action and are largely occupied in

the successful resolution of the pneumonic lesion. It is as though at the call of the organism (or nation) fixed or sedentary factory workers enlisted in the capacity of shock troops for the good of the whole.

ANDRIC AND GYNIC DIFFERENCES

There is still another set of forces within living organisms whose task concerns the complex relationships of individual and race survival. As far as perpetuation is concerned, the erotic phase of sex and the opposing genital apparatus of the two sexes adequately protect mankind from the threat of species extermination. At an earlier stage in the animal phylum, however, this danger was met by the simpler process of division, which resulted in two or more offspring, each an identical replica of the single parent. But with the establishment of bisexual reproduction, elaborate differences arose in body form and physiologic economy, characteristic for each sex. These differences are not limited to the generative organs. But throughout the entire organism, this other, or extragenital, sphere of sex is expressed as a commingling of masculine and feminine characters, known as the mosaic of androgyny.² The andric and gynec components of this mixture are distributed in varying proportion throughout the four panels of personality. The arrangement is present in every individual of either sex and plays an important role in the organism's task of self preservation. Space does not here permit a full discussion of the remarkable circumstance of maleness within the female and femaleness within the male. But it can be said that the pervasive intermixture of those two supposedly opposite biologic qualities is far more definitely and delicately balanced in the protoplasmic field than the split "psychosomatic" concept itself. There are indications now, however, that the andric and gynec differences are not opposite in character but rather covariant with different degrees of fat-muscle ratio and of oxygen consumption rates. In the matter of morphology alone the range of form from andric to gynec and the reverse is very wide.

PERSONALITY

Thus far this discussion has dealt only with the physical and physiologic qualities of protoplasms. But every one is aware that even the most lowly forms project on our consciousness an unmistakable flavor of identity. Concerning his own species, man usually speaks of the effect of this projection as the impact of personality. Moreover, because it imponderably leaps the space between its origin and the observer, we usually designate this force as a psychologic phenomenon. But the direct physical impacts of fistic blows, for example, from Joe Louis, General Tom Thumb or Einstein likewise possess easily distinguishable personal qualities.

It was because of such questions that studies in human constitution have of necessity been extended into the sphere of the psyche. Now this word, which forms the common root of psychology, psychiatry, psychotherapy and the bisecting term "psychosomatic," holds different meanings for many people. In an effort to discover what some of these connotations might be or how many men recognized a similar interpretation of the word "psyche" a questionnaire was sent to a number of physicians in each department at the Columbia-Presbyterian Medical Center. The query was simply "What does the word 'psyche' in relation to disease connote to you." The responses were varied and ranged from intentional absurdities to interested and suggestive

20. Robertson, O. H.: Personal communication to the author.

thoughts. Indeed, an analysis of them would form an illuminating commentary on the points of view of various general and special workers in medicine and surgery. But a discussion of this questionnaire is not in order here. It must suffice to state the formula which has been long in use at the Constitution Clinic. It follows: "The term 'psyche' in relation to disease connotes that quality which distinguishes a living cell or organism from a dead one. It springs with the first impregnate cell, and from the first division permeates every tissue of the entire creature, just as it vanishes in death. Psyche therefore is the life force. And this vitality is manifest only through protoplasmic response to outward or inner stimuli. Hence, in conjunction with innumerable agents of environment, the vivified or psychified protoplasm becomes one of the two essential factors which together produce different aspects of health and disease."

If we accept this definition of 'psyche', then there remains no question of the unity of the organism. We can only envision different tissue protoplasms all imbued with the same vitality interacting with one another, and the various tissues and organ systems responding in harmonious synergy to achieve whatever objective at the moment best serves the need of the individual animal itself, of which they all are parts. Any disturbance of this animated accord becomes the gateway to sickness.

That such disturbances find different expressions in different individuals who are afflicted with the same disease is well known. Thus, from time to time in acute rheumatic fever one sees a variety of manifestations in addition to the classic fever, red swollen painful joints and elevated sedimentation rate. Dermatitis marginata, for example, is a well recognized form of eruption in the disease, but it does not occur with great frequency. In those individuals who do display it, however, it must be looked on as a special constitutional criterion of that person which includes dermal cells in the organismic reaction to the impact of the rheumatic agent. That such selective tissue-cooperation responses are definitely genetic functions of cellular protoplasms is well shown by Webster's²¹ recent demonstration of the heritability of mouse brain susceptibility to the encephalitic virus.

MULTIPLE AILMENTS

In the field of internal medicine it is commonest to see patients who are subjects of one disease at a time. So that instead of the usual formula "Bill Smith 'has' pneumonia" we could perhaps more properly say "Bill Smith is partly or pretty much all pneumonia today." But there are a good many instances in which an individual patient may appear to be the subject of multiple ailments. These remarkable phenomena seem to demonstrate more forcibly than theoretical discussion the complex unity of human organism; a unity existing not only within the being of each one but also of that one within the time-spanning unity of the protoplasmic phylum.

In illustration of the foregoing notions, the following cases from the clinic are presented. The first, a married woman of 63, complained of small lumps on her face and body. The dermatologists told her they were subcutaneous fibromas which were inherited, "like birth marks." The only therapeutic offering was surgical excision. But as there were some two hundred of

the objects scattered over her body, she decided against this procedure. Incidentally, she asked at the time what could be done to relieve various other ailments. These included double ptosis of the eyelids, a curious redundancy of the scleral conjunctiva, fibroma of the uterus, mild diabetes, arteriosclerosis and occasional pain in the heart. The latter was interpreted as due to the coronary disease which eventually killed her. She was referred for each of these maladies to its appropriate special clinic, where in each instance the best treatment for that particular "disease" turned out to be unavailing. The explanation for such consistent failure, however, was found by a careful investigation of the woman's family history. It turned out that a condition of excessive overgrowth of mesodermal fibrous tissue was heavily sprinkled through the three generations studied.

The second patient, a married woman of 55, came to the hospital in a seriously ill condition. There had been a steady weight loss of 44 pounds (20 Kg.) in four years, increasing dyspnea for six months and dependent edema for four weeks. Salient points in her history were that she had insufficient food for four years as the result of economic pressure; eighteen months before admission she had developed sore throat, hoarseness and severe paroxysmal cough; recently her doctor told her that she had heart trouble; she brooded over money matters and expressed grave disappointment about her son's failure in life, and especially over his unfortunate marriage to a girl she could not tolerate.

The physical examination revealed a distraught, dyspneic woman, with rapid, overacting, totally irregular heart. The latter was slightly enlarged to the left, and there was an apical murmur. The liver edge was palpable. There were facial skin lesions of erythema multiforme. The laboratory findings proved a considerable degree of anemia; an electrocardiogram showing auricular fibrillation, a basal metabolic rate of +57, a normal sedimentation rate and a 4 plus flocculation test (Hanger).

Tentative diagnoses of thyrotoxicosis, rheumatic heart disease, vitamin deficiency and liver damage were made. But later on the picture changed so that there emerged from the complex symptomatology a clearcut pattern of hyperthyroidism. Although at first the surgical risk was not too good, the patient's response to iodine justified operation at the end of two weeks. At this time she was greatly improved, apparently as the result of hospitalization, massive vitamin intake, high caloric diet, iodine therapy and growing sense of security. No attempt had been made to assist in the resolution of her daughter-in-law conflict.

In the first of these cases one is forced to the conclusion that a genetic fault in tissue growth prevented successful interaction within the internal environment—that is, the effect of cell upon cell. It is hard to conceive that the various symptom complexes—or diseases, if you will—could each have been due to a separate reaction between psyche, in the sense of morbid energy in the unconscious, and soma. Diabetes is well known to number emotional stimuli among its etiologic factors. In this case perhaps pinching of the islands of Langerhans by inherited excessive fibrous tissue may have played an important part in the curtailment of insulin supply. It is interesting, moreover, to observe that the basic lesion in this instance did not directly involve cells of physiologically active tissue. The parenchyma was mechanically reduced in efficiency by a slow-moving tissue, whose only evidence of vitality

21. Webster, L. T., and Johnson, M. S.: Comparative Virulence of St. Louis Encephalitis Virus Cultured with Brain Tissue from Innately Susceptible and Innately Resistant Mice, *J. Exper. Med.* 74: 489, 1941.

was its capacity for growth. What the effect of the attendant miseries were on this woman's emotional patterns is perhaps suggested by the vanity reaction to facial papillomas, and the sense of frustration dependent on her physiologic handicaps.

In the second case, on the other hand, the main disturbance was in the parenchymal cells of thyroid, heart, liver and perhaps digestive mucosa. These are all directly controlled by the autonomic nervous system and respond intensely to swift waves of fear, anger, jealousy. Signs and symptoms which arise from dysfunction of such labile tissue tend to change rapidly as the functional success or failure of the involved cells varies. Consequently, even at the end of but two weeks the patient had begun to gain weight, the electrocardiogram had returned to normal and her facial expression clearly displayed greater organismic placidity. But we are as yet unable to determine the precise patterns of interaction between the energy called emotion, the energy of the chemical substance called thyroid hormone and the energy of the active cells of heart muscle, gastrointestinal mucosa, liver and thyroid gland, from which her symptoms seem to have arisen. We do know, however, that the conflicts underlying this woman's adjustment to her life still go untreated.

Biologists would look on the multiple ailments displayed by each of these women as organismic phenomena; the latter would represent disturbances of relationship within the organism between all the different protoplasms; and these in turn would express the success or failure of both phylogenetic and ontogenetic ambitions. In the first case it would seem that better breeding, a long term preventive measure, would have held the only solution to her predicament. In the second case, on the other hand, it might be contended by psychiatrists that appropriate psychotherapy could have exorcised her demons. But her heart muscle tissue was already damaged and at the danger point, so that speed for its protoplasmic relief was of the essence. That is why a kind of material therapy appropriate to the presenting state of organismic pathologic change was used immediately. Later on, perhaps, some formal psychotherapy may be profitably added. But in any event the success of all-embracing organismic treatment will depend on wisdom and skill in the choice of sequence and emphasis on method. Some of the newer advances in organismic treatment are illustrated by shock therapy.²² Ever since the early use of insulin in dementia precox the powerfully reorienting influence of protoplasmic convulsion on abnormal emotional states has been studied with increasing interest. Now that the electric shock has almost supplanted insulin, the results of such treatment for "psychic disease" have become more and more impressive. Indeed, in some cases the method seems able to accomplish in the twinkling of an eye, through effects on a wide variety of protoplasms, what many months of psychotherapy barely achieve at great cost in money, time and mental anguish for the patient. The phenomenon again supports the biologic concept of living protoplasms in continuity subserving an integrated and vital whole.

ORGANISMIC UNITY

In our current professional phrasing we are by now, no doubt, inexorably committed to the word psychosomatic. The precariousness in the use of the term, however, lies in the fact that its hoped for symbolic

connotation of unity may be lost in the false belief that two separate parts in man actually do exist. Consequently, if we examine closely the structure of organismic unity which doctors nowadays seem to be striving so hard to preserve for the individual we may find perhaps that its division resides in a contemporary medical attitude and not within the animal at all.

SPLENECTOMY IN PREGNANCY COMPLICATED BY THROMBOCYTOPENIC PURPURA HEMORRHAGICA

REPORT OF A SUCCESSFUL CASE, WITH A REVIEW OF THE LITERATURE

DAVID POLOWE, M.D.

Associate Surgeon, General Surgical Service, Barnert Hospital

PATERSON, N. J.

The patient who is the subject of this report was referred to me by Dr. M. S. Joelson when she was in her sixth month of gestation. Her chief complaints were those of widespread ecchymoses, epistaxis, hemoptysis and hematuria. Various consultations were held, a diagnosis of thrombocytopenic purpura hemorrhagica was established, and splenectomy was performed by me in the eighth month of gestation. She was delivered normally of a normal baby by Dr. Joelson about two weeks prior to estimated term. I believe this is the first case to be reported of splenectomy in pregnancy complicated by thrombocytopenic purpura hemorrhagica.

The seriousness of this complication of pregnancy is attested by the literature. Sixty-one cases have been reported singly or summarized in groups between 1867 and 1936. Mosher¹ in 1923 reported a case of his own and collected 39 other cases. He concluded that the complication of thrombocytopenic purpura hemorrhagica in pregnancy was harmful in that it was usually associated with premature delivery in the sixth or seventh month of gestation, that infection was usually superimposed on it, that the fetal mortality was 50 per cent and that the maternal mortality was nearly 100 per cent from postpartum uterine bleeding.

Of the 47 cases collected by Rushmore² in 1925 the final results with respect to the mother were recorded in 44. Of these, 26 mothers died (58 per cent). Of the 42 cases in which the final results for the infants were recorded, 27 infants died (64 per cent). Rushmore cited Puech's case in which the mother went into labor in the sixth month of gestation. Uterine bleeding continued following delivery, and the patient died from exsanguination on the second day of the puerperium.

Liebling³ in 1926 added a case in which the platelet counts were as low as 20,000, were not associated with splenomegaly, and both the mother and the infant recovered after delivery; the infant as well as the mother was affected. Mosher¹ stated that the offspring was not usually affected but was in the case he reported.

That congenital thrombocytopenic purpura hemorrhagica does occur and that it may be responsible for the infant's death in utero or within two weeks after

delivery is attested by Sanford, Leslie and Crane,⁴ who reported a case in which the mother and infant also recovered after delivery. Siegler⁵ added 12 cases to those of Rushmore,² making a total of 59 cases collected between 1867 and 1931, and added a case of his own in which the mother recovered but the infant died on

Infant's.....		420,000	16,800	5.290	17.0	

* Observations 1 to 3 made at Paterson General Hospital. Observations 4, 5 and 7 to 16 at the Barnert Hospital.
† Hemoglobin stated in milligrams per hundred cubic centimeters unless otherwise stated. Bleeding time varied on various occasions from 1½ minutes to 12 minutes. Coagulation time varied on various occasions from 5 minutes to 11 minutes. Clot retraction was reported on various occasions as being slight, no retraction after one hour, to good retraction after twenty-four hours. Tourniquet test was reported positive on the one occasion it was tried (see table 2).

the fourth day after delivery. "probably of purpura hemorrhagica," this diagnosis being based on the fact that blood was found in the spinal fluid. Necropsy of the infant was not performed.

Conti⁶ in 1933 reported a very dramatic case, with complete necropsy findings in both mother and fetus, in which splenectomy was recommended but refused by the patient. The patient suffered from severe hematuria and epistaxis. Conservative measures such as hemostatic injections and transfusions were of no avail. Just prior to death the patient suffered from amaurosis, delirium, tonic and clonic convulsions and bradycardia (pulse 52). A lumbar puncture disclosed blood in the spinal fluid.

Splenectomy in the treatment of this complication of pregnancy is suggested by Williams.⁷ Titus⁸ devotes several paragraphs to this condition and states "I have seen only 1 case of typical purpura hemorrhagica early in pregnancy, but I am impressed by the suggestion that certain fulminating types of premature separation of the placenta seem to have a definite relationship to this rare disease." It is his opinion that interruption of pregnancy will not arrest the purpuric condition. It will merely open another avenue of bleeding.

Recent opinion among hematologists, as attested by their recommendations in the case herein reported, favors splenectomy when pregnancy is complicated by thrombocytopenic purpura hemorrhagica.

REPORT OF CASE

History.—A white secundigravida aged 29 complained on Aug. 31, 1943 of ecchymoses, epistaxis, hemoptysis and hematuria. The duration of these symptoms was five years, but they had become more severe in the past month. It was estimated that she was in her sixth month of gestation at this time and that she should deliver about December 7.

The patient had been married five years, and her first pregnancy was induced prematurely in the eighth month of gestation at another hospital. Reference to the chart at this hospital (the Paterson General Hospital) indicates that the patient delivered a normal infant on Sept. 27, 1940. She had received two blood transfusions, one before and one after delivery. The blood counts taken at this time are recorded in table 1. She was discharged October 8 with a final diagnosis of pregnancy (delivered), bilateral hydronephrosis, infection of the right kidney, secondary anemia, systolic murmur and purpura hemorrhagica. The patient was advised at this time to have a splenectomy performed and not to have any more children.

The father, aged 52, had a heart attack a few years before and was now in fair health. The mother, aged 54, had had two attacks of cerebral thrombosis, which had affected her speech. Two aunts died of tuberculosis. One grandfather died of carcinoma of the stomach.

The patient suffered from a severe attack of measles, whooping cough, several attacks of tonsillitis and rheumatic fever in childhood. She had had no serious illnesses since then until five years before, when her present illness began with the appearance of ecchymoses and bleeding gums. Tonsillectomy was performed at the age of 14. At the age of 23 appendectomy was performed by Dr. Jesse H. York of Atlanta, Ga. Dr. York informed me that there was no evidence of thrombocytopenic purpura hemorrhagica at that time.

TABLE 2.—Dr. Nathan Rosenthal's Report of Sept. 28, 1943

Blood count	
Hemoglobin.....	61%
Red blood count.....	4,090,000
White blood count.....	7,200
Platelets.....	60,000
Myelocytes, neutrophils.....	2%

Plasma cells.....	1%
Erythroblasts.....	2%
Normoblasts.....	8%

"The bone marrow is markedly cellular, possibly a result of continued bleeding from time to time. The megalokaryocytes are increased and show very little tendency to maturation, typical of thrombocytopenic purpura."

The patient is group A, Rh positive.

Physical Examination.—The weight was 123 pounds (61.2 Kg.), the blood pressure 130 mm. of mercury systolic, 80 diastolic, the pulse rate 96, the heart without murmurs, not enlarged, and regular in rate and rhythm. The urine was devoid of albumin and sugar. Table 1 gives the series of blood counts taken. The positive physical findings were gestation of five and a half months, splenomegaly and widespread ecchymoses.

A diagnosis of pregnancy complicated by thrombocytopenic purpura hemorrhagica was made at this time, and immediate splenectomy was recommended and refused.

On September 28 the patient was referred to Dr. Nathan Rosenthal of New York for a hematologic study and for recommendations as to treatment. Table 2 gives the blood and bone marrow findings. He recommended splenectomy and sterilization of the patient "as soon as possible."

At the patient's request, Dr. Rosenthal's and my reports were sent to Dr. York, who in turn consulted Dr. Roy R.

Splenoma is a rare pathologic entity in which the function of the organ is not usually disturbed. Pool and Stillman¹¹ cite Foà, who in 1920 described a splenoma the size of an orange. Sweet¹² in 1942 reported the occurrence of splenoma in a woman of 59 who had had no serious illnesses. She had been married thirty-eight years and had had thirteen children and four miscarriages. Eight of the children died in infancy. Her blood count, including the platelet count, was normal. Sweet collected 7 other cases from the literature. In all these the only symptoms were those due to splenomegaly. My own case, herein reported, is unique in that some areas of the splenoma were necrotic, the blood picture was that of essential thrombocytopenic purpura hemorrhagica and pregnancy was superimposed.

Thrombocytopenic purpura hemorrhagica is a very serious complication of pregnancy. Several authorities are of the opinion that, as soon as it is established that the condition is due to splenic dysfunction, splenectomy is the treatment of choice.

SUMMARY

A case of pregnancy complicated by thrombocytopenic purpura hemorrhagica was successfully treated by splenectomy

in the eighth month of gestation. A large splenoma, with areas of necrosis, was found.

The patient was delivered normally of a normal infant about two weeks prior to estimated term.

555 East 27th Street, Paterson 4.

Clinical Notes, Suggestions and New Instruments

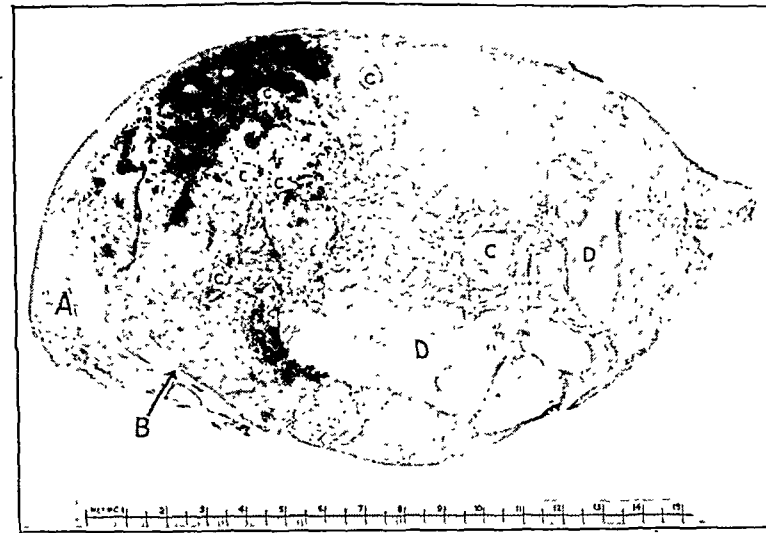

RETROPERITONEAL CAVERNOUS HEMANGIOMA

MAX MILLMAN, M.D., SPRINGFIELD, MASS.

Retroperitoneal hemangiomas large enough to have any clinical significance are so rare that practically no mention of the condition is made in standard textbooks on pathology. However, Stout¹ in his volume on human cancer cites 2 instances, 1 a case of retroperitoneal hemangioma which was mistaken for a kidney, as reported by Harris, and the other a recurring lipoma which had areas of cavernous hemangiomas in it as described by Hilse. Of the few additional cases found elsewhere in the literature almost all are of renal origin. The present case of retroperitoneal cavernous hemangioma is presented because of its large size, its extrarenal origin and its rather unusual clinical picture and course.

REPORT OF CASE

I. K., a man aged 32, married, a hardware clerk, presented himself in September 1939 complaining of generalized abdominal pains of six months' duration. His family and past histories were noncontributory. He had always enjoyed excellent health until the onset of the present illness. The pain was dull, inconstant and fairly well generalized, although somewhat worse in the left side of the abdomen, especially when the patient was in the reclining position. It was not related to food intake

Cross section of the spleen showing how the splenoma almost completely displaced the normal splenic tissue (A), the limiting connective tissue membrane of the splenoma (B), various grayish yellow nodules (C) and the large areas of necrosis within the splenoma itself (D). Only a comparatively small amount of normal splenic tissue was present at each pole.

Kracke, professor of pathology of Emory University. Dr. Kracke wrote Dr. York ". . . The problem is one of immediate management of this patient. . . . It is like trying to repair the leak in the roof while it is raining. . . . I think the best thing to do is to go ahead with splenectomy at once. . . . I don't advise sterilization in this case, since splenectomy should cure the disease."

On October 27 splenectomy was performed by me at the Barnert Hospital with the patient under a general ether anesthesia administered by Dr. H. M. Stein. The patient received 500 cc. of citrated whole blood on each of the three days prior to operation. She received 250 cc. of pooled human plasma during the operation and 500 cc. of citrated whole blood immediately after the operation.

The spleen weighed 1,060 Gm. Because it did not have the appearance usually associated with thrombocytopenic purpura hemorrhagica of the so-called idiopathic or essential type, I did not sterilize the patient.

The pathologic diagnosis (by Lieut. Jacob Churg, in collaboration with Dr. Paul Klemperer) was agnogenic myeloid metaplasia of the spleen; large "splenoma" with areas of necrosis.

On November 8 the patient was discharged, recovered, on the twelfth postoperative day.

On November 29 Dr. M. S. Joelson delivered the patient normally of a normal female infant which weighed 5 pounds 4½ ounces (2.63 Kg.). The mother was discharged one week later. The infant was taken home Dec. 22, 1943, after an epidemic of influenza in the household had subsided.

COMMENT

Splenectomy in pregnancy has been reported several times. Sutton⁹ in 1901 reported the removal of a prolapsed spleen in the second month of pregnancy, which would have given rise to serious dystocia at the time of labor had it remained in situ. Serbin¹⁰ in 1937 reported 3 cases of splenomegaly in pregnancy treated by splenectomy.

and was not relieved by alkalis or laxatives. There was no constipation or diarrhea. The appetite had remained good and there was no loss of weight. There were no symptoms referable to the cardiorespiratory or genitourinary systems.

The patient was well developed and well nourished. Abnormal findings were not present except for a large, smooth, nontender, fairly firm mass filling all of the right lower quadrant of the abdomen and extending into the right upper quadrant, where it gradually disappeared. It did not move with respiration and did not appear to be attached to the liver. The lateral border of the mass could be made out fairly well, and this was smooth in outline. The medial border, however, was less clearly defined. The blood and urine examinations were normal. The blood Hinton test was negative. X-ray examination of the chest did not reveal any abnormal findings. An intravenous pyelogram showed nothing abnormal in the kidneys or ureters. A barium sulfate enema (fig. 1) showed the cecum and ascending colon displaced obliquely as far as and even somewhat beyond the midline.

On Nov. 8, 1939 the patient was operated on, at which time a large pyramidal, hemorrhagic mass about the size of a large pineapple was found resting on the right iliopsoas muscle. The mass was soft, spongy and covered anteriorly by a thin capsule. It bled freely, and by the time it was removed it had shrunk in size considerably as the result of extravasation of blood. It was adherent quite firmly to the fatty retroperitoneal tissues as well as to the inferior part of the iliopsoas muscle. The ureter, kidney and adrenal gland were free.

The patient made an uneventful recovery from the operation. Following his discharge from the hospital he was given a series of high voltage roentgen treatments. He has since remained in excellent health. A second barium enema done

Fig. 1.—Displacement of cecum and ascending colon.

six weeks after operation showed the cecum and ascending colon to be in the normal position (fig. 2).

Microscopic examination of the tumor revealed the characteristic pattern of cavernous hemangioma. Here and there, and especially at the periphery, small amounts of fatty tissue were to be seen. The normal lobulation of fat, however, was absent.

COMMENT

The presence of fatty tissue in this tumor raises the question as to its exact origin. In Hilse's case, because of its recurrent nature, it was known that it originated as a lipoma, which later developed into a hemangioma. In our case, however, such proof is lacking. In some of the so-called cavernous

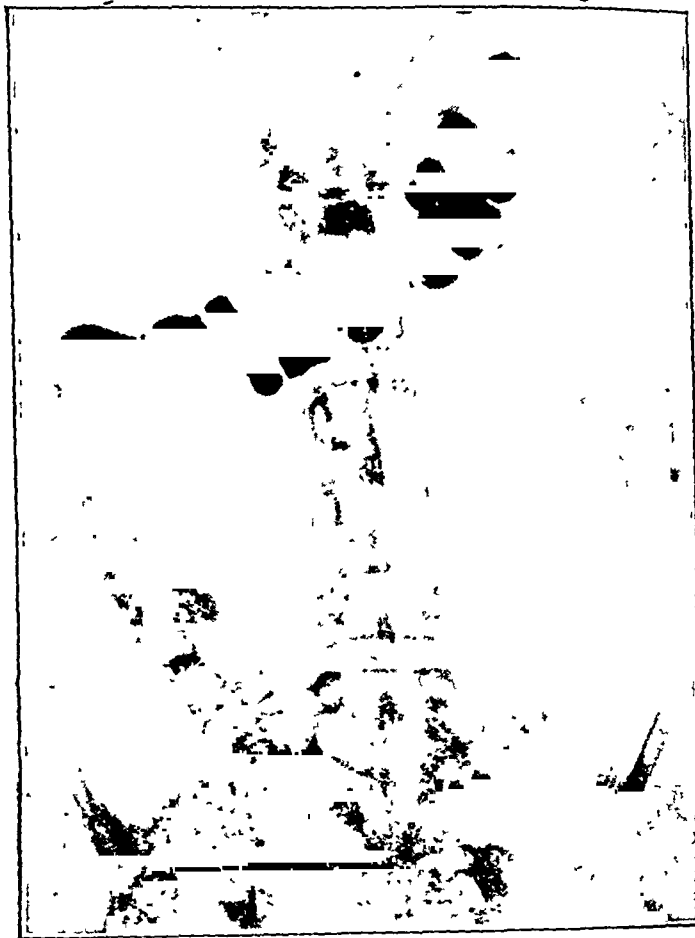

Fig. 2.—Normal position of cecum and ascending colon.

lipomas the extensive overgrowth of blood vessels may at times make it difficult to distinguish between vascular lipoma and hemangioma. However, the amount of fat in this case was too small to warrant a diagnosis of cavernous lipoma. The course of roentgen treatments was given for the purpose of preventing a possible recurrence.

ZINC PEROXIDE—A NEW DRUG FOR RAPIDLY CURING THE SWOLLEN PREPUCE

GORDON G. ALLISON, M.D., ATLANTA, GA.

Zinc peroxide (ZnO_2) is a light, white, slightly irritative, pungent, astringent, bacteriostatic powder. Unstable in water suspensions, it readily loses part of its oxygen. This zinc compound has been employed in the City Venereal Disease Clinic in over 400 cases.

Zinc peroxide was used particularly in treatment of those venereal diseases producing ulcerative lesions of the male genitals, namely syphilis, chancroid, granuloma inguinale and fusospirochetosis. The multiple and simultaneous occurrence of several of these gives rise to a swollen, nonreducible foreskin. Usually the fusospirochetes enter the picture or invade the soil and enhance the damage to the conclusion of gangrene. Those physicians in the South who deal with the Negro draftees and enlistees are all cognizant of the large number of such cases, of the urgency of prompt treatment and rapid response, of the need of prompt diagnosis and of the usual slow response or failure of ordinary measures. The use of zinc peroxide shortens the disability period, lessens pain, permits an earlier diagnosis and lowers the cost of medical care.

Inquiry into the conditions necessary for the development of a swollen edematous prepuce reveals that primarily there must be a congenital redundance to which, secondly, is added

a narrowed tip or lumen, hardened, scarred or fibrosed by former trauma or a chronic balanitis. The third factor of an active venereal infection is one far from simple; all six venereal diseases may be contributory in the pathology. Gonorrhea, syphilis, chancroid, lymphopathia, granuloma inguinale and fusospirochetosis have been found responsible; rarely one, most commonly two or three and less frequently four, five

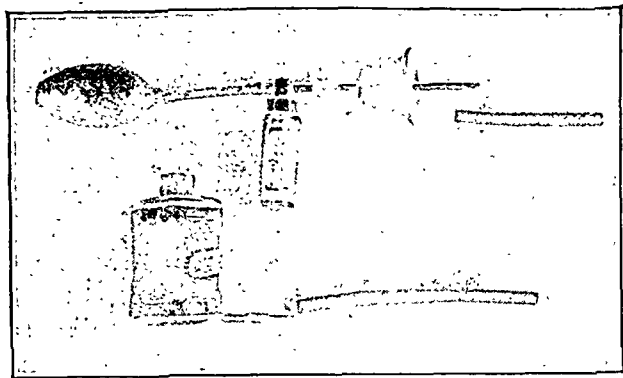

Fig. 1.—Apparatus for administering zinc peroxide.

or six are present under the same foreskin. Also various pyogenic organisms, the trichomonads and many nonpathogenic bacteria are oftentimes added to the infection.

Although the desire to reduce the swelling is paramount, one must also make a diagnosis of the venereal entity. Smears for gonorrhea, chancroid and fusospirochetosis are made at the first visit. Kahn, Frei and Ducrey tests are likewise performed. Usually the genital ulcer is visualized. The margin observed is cleaned and scraped, and a dark field examination of the serum is made. If the lesion cannot be seen, the dark field examination is postponed until swelling disappears and the foreskin can be retracted. By way of comment, it may be said that the dark field examination is frequently of no value because (1) the patient has treated himself with various drugs, and (2) if a chancre is present it is usually rather old and the spirochetes cannot be demonstrated; hence a Kahn test is usually positive at this time.

When four or five of the venereal diseases have been diagnosed in this way, treatment is begun; and after the prepuce can be retracted a small specimen for biopsy is obtained and

Fig. 2.—Method of introducing zinc peroxide.

the Donovan bodies searched for in this tissue. A second dark field examination is then made.

The method of treatment is simple. A piece of rubber tubing is attached to a powder blower or insufflator. Zinc peroxide powder is placed in the glass receptacle. The open end of the rubber tube is placed in the opening of the foreskin, and the skin is firmly held against the rubber tube. By vigorous

compression of the bulb, the powder is forcefully blown about the glans penis and under the foreskin. The secretions moisten the powder and retain it under the prepuce. The patient is instructed not to wash or irrigate himself but to return in two or three days for another treatment.

The results of this method have been most satisfactory. The secretions are immediately lessened, the edema subsides, the induration and swelling disappear, the mucosa and skin become pliant and oftentimes on the next visit the foreskin can be retracted and the underlying pathologic conditions brought into view. The hazard of gangrene and of the loss of the outer third of the penis is dissipated, the need for dorsal slits is eliminated, and, lastly, it is possible to arrive at a complete diagnosis of all the venereal diseases present.

SUMMARY

A method of employing zinc peroxide to relieve a swollen prepuce caused by one or more venereal diseases has been devised. The efficacy of this method has been proved in over 400 cases. Its value is pertinent in these war days to all dealing with enlisted men, draftees and defense workers, particularly those of Negro blood.

BLOOD GROUPING EVIDENCE

In courts of law any child born in lawful wedlock is presumed to be legitimate, and from the earliest days this presumption of legitimacy has been an extremely weighty one. Under the law of the "four seas" an English court once held that a child born in England was legitimate even though it appeared from the fullest evidence that the husband resided in Ireland during the whole term of his wife's pregnancy and for a long time previously, because Ireland was within the king's domain.¹ In 1907 this grotesque rule was modified, but the presumption of legitimacy has remained a formidable obstacle to scientific progress, as may be gleaned from a recent decision handed down by an English court.²

In a divorce proceeding the husband requested a blood test, which proved that he was not the father of his wife's child. (Both husband and wife belonged to type M, while the child belonged to type MN.) The test is now generally accepted as proof that a certain man could not have been the father of a certain child. In his decision the judge remarked that at first he was inclined to think, *albeit very reluctantly* (italics ours), he was bound in law to accept the result of the blood group test, not because as a man he thought the doctor was right but because as a magistrate he thought the evidence was legally convincing. However, since the legal presumption of a child born in wedlock being legitimate is very strong, he finally decided not to upset it solely on scientific evidence. Evidently this judge preferred the comfort of adherence to tradition.

The reaction of American courts to blood test evidence has been reviewed in a book that has just appeared.³ The problem of paternity arises most frequently in so-called filiation proceedings, less often in divorce actions. In the former the child is born out of wedlock and the mother designates a certain man as father and

an action is started to compel him to support the child. In such cases, when the blood tests prove that the defendant is not the father of the child in question, the courts usually accept this result without hesitation, probably because an illegitimate child is involved. (It is highly significant, that the woman usually confesses to indiscretion with other men besides the defendant after the results of the blood tests are divulged.) In uncontested divorce actions the reaction of the court is likewise favorable. In contested divorce actions, on the other hand, judges apparently prefer to accept the testimony of the wife rather than the objective blood test findings, so that in courts of this country, just as in England, not much progress has been made away from the law of the "four seas."

No doubt the first duty of the court is to see that truth and justice prevail. In the English case cited, the court proudly announced the happy outcome—the husband agreed to make a home for wife and child and accept the child as his own. However, a reconciliation might have been effected without resorting to such subterfuge, because husbands in the past have been known to forgive erring wives and to accept children not their own. When a court refuses to dissolve or annul a marriage of two completely incompatible people, even though there is scientific proof of the wife's deceit or fraud, as has happened in a number of cases in American courts, the court would not appear to be carrying out its responsibilities as an administrator of justice.

ANDREAS VESALIUS AND HARVEY CUSHING: TRADITION AND INSPIRATION

Just as skill in perspective drawing is necessary for proficiency in painting and sculpture, a mastership in anatomy opens the door to all purposeful work in medicine. The period of Galen, emphasizing rational anatomy and physiology as a corrective to even the brightest hippocratic philosophies of form and function, significantly runs synchronously with the highest development in Greek art. Galen's inductive school dominated practically all natural and medical science until the advent of the Renaissance, when medicine, till then a unit, burst into the cluster of component disciplines natural history, physiology, geology, chemistry, physics, astronomy and mechanics. When Vesalius in the sixteenth century instituted the teaching of anatomy by dissections of the human body, the laboratory method recorded its first victory over the didactic. No wonder, then, that the name of Andreas Vesalius took a high place in medical consciousness.

In those early days the study of nature flourished under the wing of medicine. As a reminiscence of that fostering care, the study of the medical sciences now leans on a competent insight into all nature and a knowledge of the methods and results of the former

auxiliary disciplines. For that reason all medical men may be said to enter medicine by an introduction into the natural sciences now known as biology. Many of the greatest medical men have been historically minded. American activity in the history of medicine compares well with similar scholarship elsewhere. An enthusiastic group of physicians have supported it with both international and local studies, receiving loyal aid from capable bibliographers and collectors of medical literature. Nor should those publishers be forgotten who, time and again, took risks in order to stand by the traditions which history and biography try to maintain.

Many will remember the time when medical-biologic libraries of adequate size were scarce enough even in important medical centers in the United States. The progress of our library movement has been effective. Two classes of books are permanently valuable for medical research: periodicals and the classics in all general, special and contingent fields. Library service grew as the books accumulated; local service and countrywide cooperation now are demanded, observed and explored. The spread of bibliographic assistance is an example to all the world. From the Surgeon General's *Index Catalogue* through the *Index Medicus* to the *Quarterly Cumulative Index Medicus*, bibliography has proceeded in a purposeful organization of collective efforts toward the support of medical scholarship.

John Shaw Billings conceived the anatomic analysis of the Surgeon General's Library which now is being continued by the library staff of the American Medical Association. Osler, Welch, Garrison, Crummer, Pilcher, Frank and Cushing, as well as their still surviving spiritual descendants, carried this analysis into the field of critical history by analyzing the contents and significance of known and newly discovered classics. Harvey Cushing pursued bibliologic studies in his scant hours of respite between operations. His latest effort in the field of historical medicine was his work *A Bio-Bibliography of Andreas Vesalius* (New York, Schuman's, 1943). At the age of 29 Vesalius published (1543) his monumental work on human anatomy, with its unexcelled engravings, renowned artistically no less than scientifically, and accompanied by elaborate descriptions, which soon became familiar to every student in every medical group in Europe. The illustrations were copied, reprinted and appropriated by numerous contemporary and later writers. This tradition Dr. Cushing, during forty years of a busy life, traced in full detail, collecting, comparing and defining the influence of Vesalius through the ages. The findings of many other bibliographers were verified and ventilated. As a result the restless life of Vesalius unfolds before us. The reader learns about his book on the China root, his *consilia* (written consultations), his discussions of the findings of Fallopius, his emendations to Galen, his

epistle on venesection, some of these papers being side lights to his major work.

All this constitutes the life of a medical scholar of transcendent influence. This indeed is history. Vesalius is not the only person to whose abilities this book testifies; Harvey Cushing persisted in this work until the pen dropped from his capable hands.

IS ASPIRIN A DANGEROUS DRUG?

Aspirin, or acetylsalicylic acid, has been used in enormous quantities throughout most of the world for some forty-five years. Many persons seem to have a mild idiosyncrasy to this drug or to the other salicylates and consequently avoid its use; the vast majority take it with apparent impunity. Although toxic effects have been discussed in these columns,¹ severe reactions are certainly rare in relation to the enormous quantities consumed. Deaths from aspirin have been reported; these appear to have been more frequent in England than in this country.

New evidence indicates that aspirin and the other salicylates produce a physiologic effect which cannot be ignored. About 1941, Huebner and Link² of the Wisconsin Agricultural Experimental Station discovered that dicumarol when given by mouth induces a shortage of prothrombin in the blood. They found also that dicumarol could be qualitatively degraded to salicylic acid. Later, Link and his co-workers³ tested the action of salicylic acid itself. When single doses of salicylic acid were given to rats kept on an artificial diet which was low in vitamin K, a decrease of the prothrombin in the blood occurred. Also if the salicylic acid was given over a long period, hemorrhages resulted; if vitamin K was administered the hypoprothrombinemia did not develop. More recently other investigators⁴ found that salicylic acid would act in the same way on human beings and that when vitamin K was administered simultaneously with the salicylic acid the fall in prothrombin levels was prevented. The administration of vitamin K after the production of hemorrhage by dicumarol or salicylic acid, however, is of little use.

These observations offer a plausible explanation of such events as the report of a British physician⁵ in 1943 concerning the development of nosebleed in 3 cases after taking large doses of aspirin or the frequent occurrence of bleeding in patients with rheumatic fever who are receiving large doses of salicylates. Such

observations suggest that patients who are required to take salicylates in large quantities for a long time should also receive prophylactic doses of vitamin K. When, however, hemorrhages occur after the taking of dicumarol or the salicylates, vitamin K is not likely to be effective; then proper treatment may include the giving of a blood transfusion.

The mass of evidence so far available indicates that aspirin and the salicylates are among the least toxic of active pharmacopeial preparations. This status, however, should not be interpreted as an excuse for failure to recognize hazards connected with their abuse or even under certain circumstances of established usage. Their ability to produce hemorrhage in some cases appears to be counteracted by early administration of vitamin K. It does not now seem necessary to administer vitamin K to all patients receiving salicylates; those who are to receive large doses for a long time may appropriately be given vitamin K.

Current Comment

PNEUMONIA IN THE SHIPBUILDING INDUSTRY

The United States Maritime Commission calls attention to the observations of Collen, Dybdahl and O'Brien that welders are no more prone to respiratory disease than other shipyard workers. In the twelve month period from September 1942 to September 1943 864 patients with pneumonia were treated at the Permanente Foundation Hospital, Oakland, Calif. The diagnosis of pneumonia was substantiated in every case by a positive roentgenogram of the chest. Questionable cases of "minimal" pneumonia, "pneumonitis" or similar indefinite diagnosis were not included in this series. Patients with pneumonia as a contributory diagnosis to another illness were excluded. A study of the epidemiology of pneumonia at the shipyards indicated that the annual frequency rate of pneumonia was 9.5 per thousand workers. Available data did not indicate that the rate of incidence or type distribution of pneumonia were different among shipyard workers than in the general population. Workers who had recently migrated to this area from other states were no more susceptible to pneumonia than those who have lived in this region for a long time. The incidence rate of pneumonia was found to be independent of the length of employment. There was no relationship between the incidence of pneumonia and occupation. Since pneumonia is commonly accepted as an index of both the seriousness and the general occurrence of severe respiratory illness, it is important to the steel fabrication industry in general and especially to the shipbuilding industry that these observations be known. Complete details are available from the Division of Shipyard Labor Relations, U. S. Maritime Commission, Washington, D. C.

MORE ELECTRICAL TRANSCRIPTIONS FOR RADIO PROGRAMS

On page 784 of this issue of THE JOURNAL is an announcement of electrically transcribed radio health broadcasts available through the Bureau of Health Education. This project was authorized by the Trustees for experimental development in 1942. Since that time three series of electrically transcribed programs have been made available and a fourth is in process of development. These electrical transcriptions are in the form of interviews with physicians of the headquarters staff of the American Medical Association, who are interviewed by women broadcasters. In view of the reduced membership of local medical societies owing to the war situation, the maintenance of radio broadcasting service in local communities has become impossible on a normal basis. The use of radio scripts furnished by the Bureau of Health Education for many years has dwindled sharply because of the lack of physicians in local communities to organize and maintain a broadcasting service. Electrically transcribed radio health broadcasts now available can be used in local communities with a minimum of time and effort by local physicians and county medical societies. In many instances all necessary arrangements can be made by the Woman's Auxiliary. No matter at what time of day the radio station makes time available, the transcription is always ready. Local medical societies, health departments, voluntary health agencies or any reputable local group may have these transcriptions, subject to approval by the local medical society, without cost except for the nominal expense of returning the records. Already these transcriptions have been lent more than fifty times and have served in more than twenty-five communities. Many of the sets of records that have been lent will be returned to the Bureau soon and will be available again for use.

PREVENTION OF VENOUS THROMBOSIS

The discovery that dicumarol reduces the prothrombin titer of circulating blood¹ stimulated the hope that this active principle of sweet clover toxin might be useful in the prevention or cure of venous thrombosis. This hope was strengthened by preliminary tests which showed that lethal doses of this toxin reduced the incidence of experimental thrombosis in dogs. Dale and Jaques² administered 10 mg. of dicumarol per kilogram intravenously to a number of dogs and sixty hours later crushed their radial and saphenous veins with linen thread. Two and one-half hours after removal of the ligatures 60 per cent of the injured veins were found free from thrombi, as contrasted with a 100 per cent involvement in their nonintoxicated controls. Richards and Cortell³ gave 4 dogs lethal oral doses of dicumarol (25 mg. per kilogram) daily for three to five days and then attempted to produce thrombosis by injecting

1. Link, K. P., and others: J. Biol. Chem. **136**: 47, 1940; **138**: 1, 21, 513, 1941; **142**: 941, 1942.
2. Dale, D. N., and Jaques, L. B.: Canad. M. A. J. **46**: 546, 1942.
3. Richards, R. K., and Cortell, R.: Proc. Soc. Exper. Biol. & Med. **50**: 237, 1942.

monoethanolamine oleate into isolated loops of their radial and saphenous veins. Six to ten days later the veins were examined microscopically. Thrombi were absent in 10 of the 12 sclerosed veins of the dicumarol intoxicated dogs, while thrombi were found in 11 of 14 sclerosed veins in their nonintoxicated controls. Thill and his associates⁴ of the University of Wisconsin, using the same sclerosing method, tested the prophylactic efficiency of a single safe therapeutic dose of dicumarol. Each of a series of 15 dogs was given 5 mg. of dicumarol per kilogram orally in a gelatin capsule, 15 untreated dogs being used as controls. Two days later the average prothrombin time was twenty minutes in the dicumarol treated dogs as contrasted with six minutes prothrombin time in their untreated controls. Monoethanolamine oleate (0.25 cc.) was then injected into a 3 inch isolated segment of each radial vein of the 30 dogs. Three minutes later the finger compressions above and below the isolated segments were removed and the sclerosing agent permitted to enter the general circulation. Six to nine days later the segments were studied microscopically. In the 15 untreated controls 17 (56.6 per cent) of the 30 sclerosed veins showed thrombi. Only 6 (20 per cent) of the 30 sclerosed veins showed thrombosis in the 15 dicumarol treated dogs. The incidence of experimental thrombosis was therefore reduced over one half as a result of a single therapeutic dose of dicumarol. This dose is equivalent to the amount that can be safely administered to man. Neither postoperative hemorrhage nor other deleterious effects were noted as a result of administration of dicumarol in this dosage.

DIAGNOSIS OF SUBDURAL HEMATOMA IN CHILDREN

The need for early diagnosis and prompt treatment of subdural hematoma in children cannot be overemphasized. By restricting the rapid expansion of the brain which occurs at this age period and by interfering with the blood supply and cerebrospinal fluid circulation, subdural hematoma impairs the development of cortical functions and leads to degenerative and atrophic changes of the brain. Cortical atrophy, optic atrophy, extensive paralyzes and mental deterioration are some of the irreversible complications resulting from uncontrolled subdural hematoma. Yet the condition is often unrecognized. Of 98 cases studied by Ingraham and Matson,¹ only about one third were hospitalized with the correct primary diagnosis. The usual belief that this lesion seldom occurs, in addition to the lack of a characteristic clinical picture, is largely responsible. In this connection Ingraham and Matson point out that the frequency with which subdural hematoma is found is largely proportional to the intensity with which it is sought. In the presence of any indication of subdural hemorrhage, puncture of the subdural space, they recommend, should be performed to establish a definite diagnosis. This

implies, of necessity, that the lesion must be suspected and sought for, as there is no other indication for subdural puncture. In 98 cases of subdural hematoma in children, the most constant features were generalized symptoms such as irregular fluctuations of temperature, failure to gain in weight, vomiting and irritability. Signs referred to the central nervous system, including hyperactive reflexes, paralysis, convulsions and coma, were sometimes present. More specific signs of intracranial hypertension, such as progressive enlargement of the head, separation of the cranial sutures and abnormalities of the eyeground were significant indications for doing subdural puncture. However, the clinical picture was frequently misleading, being that of an infant appearing acutely or chronically ill, with an elevated or subnormal temperature and malnutrition. A history of trauma to the head should then be carefully investigated, as it was present in over half of the patients. The fact that only 11 had skull fracture indicates that mild trauma might well account for many cases of subdural hematoma in children. In all cases, definite diagnosis was possible by the results of subdural puncture, which, performed with aseptic care, is a simple and safe procedure.

EARLY RECORD OF VITAMIN C DEFICIENCY

Perhaps the earliest recorded example of vitamin C deficiency was that described in himself by Luigi Cornaro in 1558. According to Marcovitch,¹ Cornaro restricted his diet to bread, the yolk of egg and a little meat, together with 14 ounces of wine. During July and August of each year he suffered from anorexia, but as soon as new wine became available his symptoms improved. In the light of modern knowledge this may be interpreted as evidence of vitamin C deficiency, since it is now known that wine, never overplentifully supplied with this vitamin, contains none at all after it becomes a year old. During periods of vitamin C deficiency, Cornaro frequently ate only the yolk of an egg; since carbohydrates create a demand for vitamin C that is not made by proteins or fats, he thus showed himself to be a keen observer and an astute selector of suitable food.

EXPECTATION OF LIFE

The League of Nations Monthly Bulletin for December presents tabular data on the expectation of life at birth and at 1 year of age in over thirty countries. For all countries covered the expectation of life at birth and in the earlier years of life is greater than in previous periods; the improvement is less striking or absent in later stages of life. The United States ranks high in the list and is exceeded only slightly by the Netherlands, New Zealand, Australia and Sweden. Japan, Russia and India have the lowest expectation of life, according to the latest information available. In all countries females show a greater expectation of life than males.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession.

ARMY

COORDINATION OF PHYSICAL AND SURGICAL THERAPY IN ORTHOPEDIC AND AMPUTATION CASES

The War Department states in the Technical Bulletin of Medicine No. 10, dated February 14, that in order that the care of orthopedic and amputation cases may be of the highest order, treatment by responsible medical officers and physical therapists must be more closely coordinated. Such coordination can be effected by the attendance of physical therapists at ward rounds and at clinical orthopedic conferences at which the diagnosis, clinical history and proposed therapy in each case are discussed by the ward officers and section chiefs.

An active program of muscle development and rehabilitation during convalescence is essential. More careful attention during the early postoperative period should be given to special exercises of the muscles of the abdominal wall, extremities and back. By their use all patients requiring prolonged periods in bed, including those in casts, can prevent the development of muscle weakness and atrophy.

The importance of quadriceps muscle treatment is too frequently disregarded. This has been responsible for poor postoperative results, especially in cases of internal derangement of the knee joint. Preoperative instruction of the patient in regard to exercises to be carried out following surgery should be given. The prescribed exercises should be begun as early as forty-eight hours after surgical operation and should be graduated to include, successively, static contraction, straight leg raising, active motion and resistive exercises. Full weight bearing must not be permitted until the strength of the quadriceps is adequate. Grouping of patients with allied conditions will facilitate instruction and promote interest and a spirit of competition in the proper performance of the prescribed exercises.

Massage should be employed only in those cases in which it is definitely indicated and should never be carelessly or hurriedly administered. Such therapy is a valuable supplement to active exercises but not a substitute for them.

In the case of peripheral nerve injuries particular attention should be given to muscle testing and tests for sensory changes. The progress of these cases can be followed only when this information is well known to both the medical officer and the physical therapist.

In regard to the treatment of anterior poliomyelitis, the principles of support, splinting and therapeutic exercise have been presented in SGO, Circular Letter No. 175, dated Oct. 20, 1943, and published in THE JOURNAL, Nov. 27, 1943, page 841.

MILLION SOLDIERS MADE DENTALLY FIT BY ARMY DENTAL CORPS

Approximately 1,000,000 men have been rendered dentally fit by the Army Dental Corps for general military service since the start of the war, according to a recent release from the War Department. Accepted into the Army under lowered dental requirements, these men were treated by the Army Dental Corps to correct defects, cure dental diseases and provide dentures. Dental requirements were lowered in October 1942, since which time about one man in a thousand has failed to meet maximum dental requirements. Since Pearl Harbor, more than 1,075,000 new dentures have been furnished and Army personnel have had more than 31,142,000 teeth filled. More than 56,000 bridges, 220,000 denture repairs and 323,500 prophylactic

and pyorrhea treatments have been provided. During the latter months of 1943, 30 per cent more teeth were replaced by dentures and bridges than were extracted by the Dental Corps. It is estimated on the basis of past experience that there will be a minimum of 60 extractions for each hundred men inducted, and about 15 new dentures. The average man will require five or six fillings, in addition to various other dental services. About 3.5 per cent of newly inducted personnel wear one or more dentures.

SLEEPING BAG FOR EVACUATION OF WOUNDED

A new type of sleeping bag has been designed and developed by the Quartermaster Corps for evacuation of wounded under conditions of extreme cold, the War Department recently announced. The new sleeping bag will be used by Army Air Forces for air evacuation at high altitudes, and by Army Ground Forces in ambulances operating in arctic and subarctic areas. It consists of two mattresses held together by a 20 foot long slide fastener with ten separate sliders. The outside of the bag is of water repellent duck and the inside is of cotton balloon cloth. It weighs about 24 pounds, is quilted and is stuffed with feathers, and has six carrying loops. The bag may be opened out flat for cleaning and airing by bringing all ten sliders together on one side. When occupied and closed, use of any of the ten sliders permits easy access to any part of the wounded man without entirely exposing him. Another 32 inch fastener with three sliders permits opening the bag down the front, including an arrangement for a face opening. A face opening also may be made at one side for patients who must be transported lying on one side.

NEW FRONT LINE SURGICAL TRUCK

A new type of surgical operating truck, the idea of Major Gen. Norman T. Kirk, Surgeon General, U. S. Army, which enables several army surgical teams at the front lines to work at the same time with the result that from 80 to 100 men can be operated on during a full twenty-four hours, was announced by the War Department February 23. Numerous units have already been manufactured and sent overseas. The truck is six wheeled and has a 2½ ton capacity. The teams work in tents attached like two rooms to the rear of the truck. The tent rooms are double walled and lined in white duck to give light. Screened windows give added illumination. The inside of the truck is used for the storage of supplies, instrument cabinets and scrub sinks. In the old type surgical mobile unit, still in use where it meets the need satisfactorily, only one team can work at a time. Operations are performed in the truck. A tent attachable to it can be used only for receiving and delivering patients.

BANDAGING AND SPLINTING

The War Department has issued a field manual numbered FM 8-50 on bandaging and splinting. It offers a complete discussion of basic materials, the use of triangular and cravat bandages, roller bandages, dressings and splints, also instructions regarding the Balkan frame. The manual is planned primarily as a guide to medical officers and noncommissioned officers concerned with instructing medical department personnel. Copies may be obtained from the Government Printing Office.

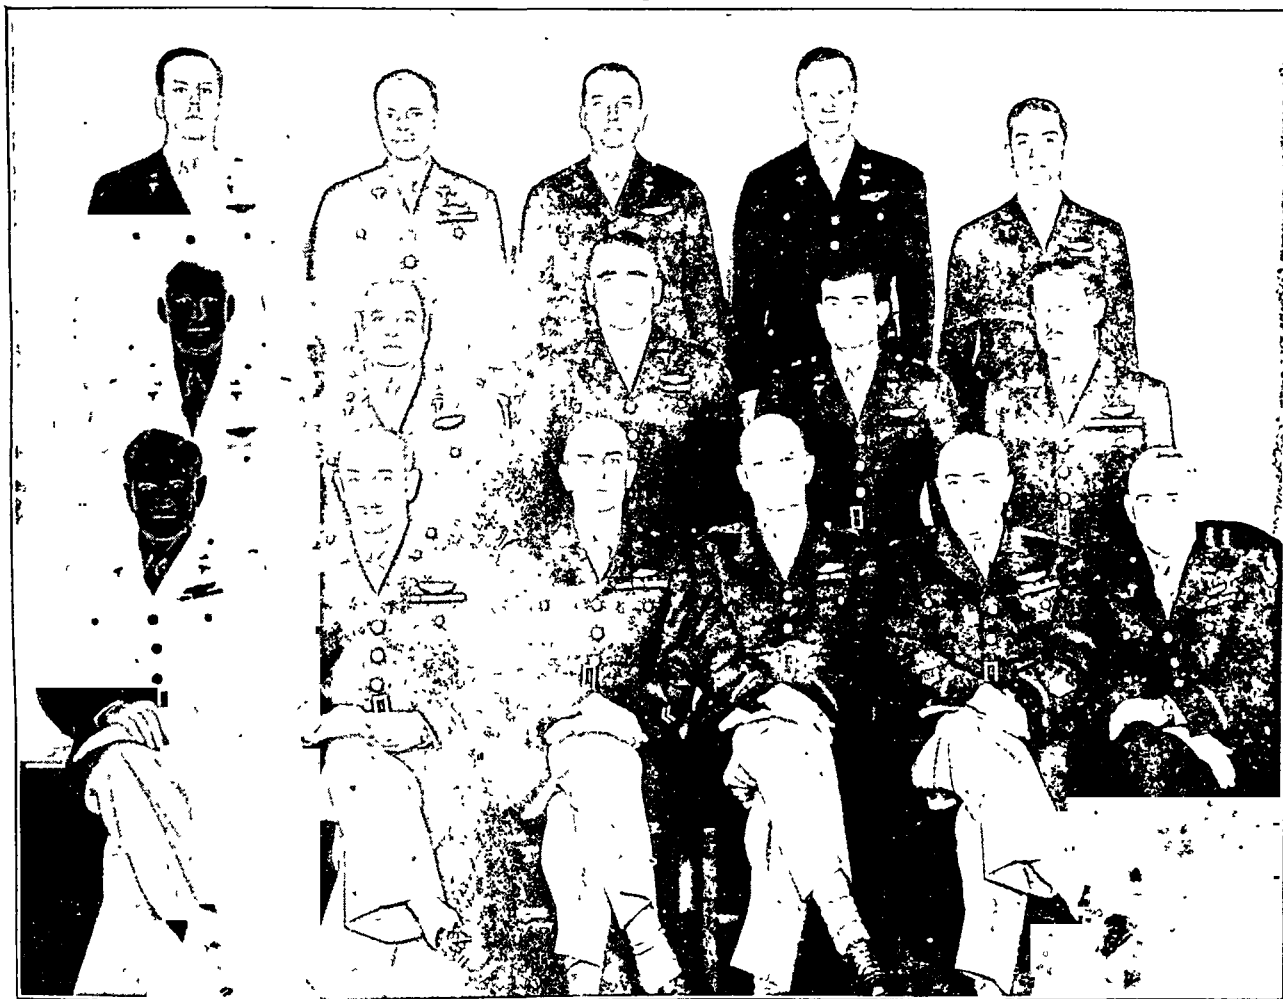

ARMY AIR FORCE SURGEONS

A meeting of surgeons from all U. S. Army Air Forces Commands and Air Forces within the continental limits of the United States was held from January 20 to 23 in the office of the Air Surgeon, Washington, D. C. In the accompanying illustration, reading from left to right, are shown the following officers:

Front row: Col. E. F. Harrison, surgeon, AAF Central Flying Training Command, Randolph Field, Texas; Brig. Gen. Eugen G. Reinartz, commandant, AAF School of Aviation Medicine, Randolph Field, Texas; Major Gen. D. N. W. Grant, the Air Surgeon; Brig. Gen. Charles R. Glenn, surgeon, AAF Training Command, Fort Worth, Texas; Col. Cadmus J. Baker, surgeon, First Air Force, Mitchel Field, N. Y.; Col. Fabian L. Pratt, surgeon, Fourth Air Force, San Francisco.

HONOR STUDENTS IN ARMY SPECIALIZED TRAINING PROGRAM AT WAYNE UNIVERSITY

Forty-five honor students in the Army Specialized Training Program, comprising the upper fifth of their class scholastically, received certificates of merit at a military review held recently at Wayne University. At the ceremony, Lieut. Col. Chester A. Marr, commanding officer of the Detroit technical training area, and Capt. Walter A. Cook, Capt. Keith Murdock and Lieut. Philip E. Goslee, all ASTP officers, represented the army. The university was represented by Dr. David D. Henry, executive vice president; Dr. William W. Whitehouse, dean of the College of Liberal Arts; Victor F. Spatheld, counselor in men's activities; Don Palmer, counselor of placement, and Howard Hess, assistant professor of electrical engineering.

Surgeons of Army Air Forces at meeting in Washington.

Second row: Col. Harold H. Twitchell, surgeon, Second Air Force, Colorado Springs, Colo.; Col. John M. Hargreaves, surgeon, Air Service Command, Patterson Field, Ohio; Col. Michael G. Healy, surgeon, AAF Western Flying Training Command, Santa Ana, Calif.; Col. Wilford F. Hall, surgeon, AAF Western Technical Training Command, Denver; Col. Paul C. Gilliland, Air Transport Command, Washington, D. C.

Third row: Col. Kenneth G. Gould, surgeon, Third Air Force, Tampa, Fla.; Col. Nuel Pazdral, surgeon, AAF Eastern Flying Training Command, Maxwell Field, Ala.; Col. Dan C. Ogle, surgeon, AAF Regional Station Hospital No. 1, Coral Gables, Fla.; Col. Ralph T. Stevenson, commandant, AAF School of Air Evacuation, Bowman Field, Ky.; Col. William H. Powell Jr., officer in charge, Professional Services, Headquarters AAF Training Command, Fort Worth, Texas.

CAPT. SHELDON C. SOMMERS AWARDED SILVER STAR

Capt. Sheldon C. Sommers, formerly of Indianapolis, has been awarded the Silver Star for heroism in action in Italy. The citation accompanying the award read "Under heavy enemy shell fire, Captain Sommers left his position of safety to care for several men who were wounded by an enemy burst. During this period Captain Sommers was under heavy artillery fire. After the wounded were treated and evacuated, he found that several unseasoned troops were becoming panic stricken. He calmed them and got them to return to their positions. Captain Sommers' action reflects great credit on the medical service." Dr. Sommers graduated from Harvard Medical School in 1941, interned at the University of Chicago Clinics and entered the service July 30, 1942.

CAPT. RICHARD F. KUHN AWARDED MEDAL OF DISTINCTION BY THE BEY OF TUNIS

Capt. Richard F. Kuhn, formerly of Detroit, has been awarded the Medal of Distinction by the Bey of Tunis in recognition of the medical aid he gave to Tunisian civilians while serving as a flight surgeon for the Red Devil Flying Fortress Squadron. Dr. Kuhn, now serving in Italy, was given the high award comparable to the U. S. Distinguished Service Medal by a French general, according to a letter received by Dr. Kuhn's parents. Dr. Kuhn graduated from Wayne University College of Medicine, Detroit, in 1938 and entered the service in June 1942.

MEDICAL REPLACEMENT TRAINING CENTER

Brig. Gen. Raymond W. Bliss, director of the operations division for the Surgeon General, addressed several hundred graduates of the School for Medical Officers at the Medical Replacement Training Center, Camp Barkeley, Texas. The ceremonies marked the completion of a six week indoctrination course for the officers and the first time that such a course was offered at a medical replacement training center, where all facilities for diversified training are offered. The course stressed physical conditioning and field work.

NEW RADIATION THERAPY SECTION AT ARMY MEDICAL CENTER

Ceremonies marking the opening of the new Radiation Therapy Section of the Army Medical Center were held March 10 in the Red Cross Building, Washington, D. C. The opening address was made by Major Gen. Shelly U. Marietta, and papers were presented on The Cancer Problem in the Army by Brig. Gen. Fred W. Rankin, The Treatment of Cancer in an

Army General Hospital by Lieut. Col. Rettig A. Griswold, The Development of Supervoltage Roentgen Rays by Major Milton Friedman, and The Postwar Cancer Problem by Dr. R. R. Spencer.

NEW OFFICERS OF THE AMERICAN MEDICAL SOCIETY ETO

At the annual meeting of the American Medical Society ETO, held at the headquarters, Eighth Air Force, the following officers were elected for the year 1944: Col. Herbert B. Wright, headquarters Eighth Air Force, president; Major Paul C. Morton, 49th Station Hospital, vice president; Lieut. Col. Theodore L. Badger, 5th General Hospital, secretary-treasurer; Lieut. Col. M. T. Kubin, 16th General Hospital, and Capt. Howard W. Rogers, 28th Division, executive committee.

CAPT. JOSEPH E. SCHENTHAL AWARDED LEGION OF MERIT

Capt. Joseph E. Schenthal, formerly of Baltimore, has been awarded the Legion of Merit by order of Lieut. Gen. George H. Brett, commander of the Caribbean defense area. The citation accompanying the award read "Captain Joseph E. Schenthal, Medical Corps, Army of the United States. For exceptionally meritorious conduct in the performance of outstanding service from Jan. 29, 1942 to March 9, 1943, as surgeon of a Coast Artillery regiment. From the beginning, Captain Schenthal displayed an extraordinary interest in his problems and particularly that of combating malaria. Largely due to his personal interest and efforts, high professional skill and devotion to duty, he was responsible to a marked degree for the sharp decrease in the malarial rate of his regiment." Dr. Schenthal graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1939 and entered the service June 1, 1941.

NAVY

NAVY DOCTORS FIND TONS OF MEDICAL SUPPLIES AT CAPE GLOUCESTER, NEW BRITAIN

Navy doctors attached to the Marine regiment that took the air fields from the Japanese at Cape Gloucester, New Britain, found tons of medical supplies, much of them in usable condition. Vitamin concentrates and drugs were destroyed, however, because of their unknown quality and strength. Prized finds were surgical and dental instruments, many of which had been plundered from army hospitals in the Philippines. Lieut. Joe P. Page, U.S.N.R., a dentist, exhibited a contra-angle handpiece for dental drills manufactured by S. S. White Dental Manufacturing Company. Neatly packed in a wooden box, stripped with metal, was a set of forceps and dental picks. Large boxes of gauze and cotton were salvaged by Marine quartermasters. Lieut. Comdr. Richard M. Forsythe, a former resident in surgery at Grasslands Hospital, Westchester County, N. Y., found a tracheotomy set for throat surgery and well packed anesthesia sets for parachute dropping. Some quinine of known quantity was salvaged. A German product similar to atabrine, a malaria preventive, is being tested for possible use there.

LIEUT. COMDR. TOM T. FLAHERTY RECEIVES SILVER STAR MEDAL

Lieut. Comdr. Tom T. Flaherty, formerly of Long Beach, Calif., has been awarded the Silver Star Medal. The citation accompanying the award is as follows: "For conspicuous gallantry and intrepidity in action while evacuating wounded aboard a Naval Transport Plane, attached to Marine Air Group Twenty-Five, operating in the Solomon Islands Area, Sept. 14-15, 1942. Flying in a cargo plane with emergency supplies to Henderson Field, Guadalcanal, to assist in evacuating wounded personnel, Lieutenant Commander Flaherty (then Lieutenant) courageously remained at his post despite continual

bombing and strafing of the field by enemy aircraft, supervising and aiding in the loading of the wounded who were under his care. His fearless and untiring devotion to duty was in keeping with the highest traditions of the United States Naval Service." Dr. Flaherty graduated from the University of Southern California School of Medicine, Los Angeles, in 1939 and entered the service in August of that year.

THE NEW BRONZE STAR MEDAL

The Secretary of the Navy recently authorized that the ribbon bar for the new Bronze Star Medal, established February 4 by the President of the United States for both the United States Army and the United States Navy, will be Old Glory Red with an eighth-inch stripe of Royal Blue in the center with white piping on each side of the blue and at the edges of the bar. The ribbon bar will be $1\frac{3}{8}$ inches wide and $\frac{1}{2}$ inch long. The purpose of the new medal, which takes precedence next after the Navy and Marine Corps Medal and next before the Air Medal, has been described by the President, which description follows in part:

"There is hereby established the Bronze Star Medal . . . for award to any person who, while serving in any capacity in or with the Army, Navy, Marine Corps or Coast Guard of the United States on or after Dec. 7, 1941, distinguishes or has distinguished himself by heroic or meritorious achievement or service, not involving participation in aerial flight, in connection with military or naval operations against an enemy of the United States."

NAVY PERSONAL

The Navy Department recently announced the promotion of Rear Admiral Ross T. McIntire, Surgeon General of the Navy, to the rank of Vice Admiral.

MISCELLANEOUS

PROCEDURES GIVEN FOR SELECTING
A. S. T. P. MEDICAL, DENTAL
AND VETERINARY
TRAINEES

As recently announced by the War Department, soldiers who remain in the Army Specialized Training Program after April 1 will be primarily those assigned to courses in medicine, dentistry, veterinary medicine and advanced engineering.

Procedures governing selection of medical, dental and veterinary trainees were announced on March 2. Meanwhile, procedures for the selection of trainees in engineering and foreign area and language to be retained now are under consideration. In addition, broad expansion of the Army Specialized Training Reserve Program is contemplated, with details to be announced publicly soon.

Enlisted men now assigned to the Army Specialized Training Program for instruction in medicine, dentistry and veterinary medicine will be continued in the program. Also Army Specialized Training Program soldiers currently enrolled in preprofessional courses will be continued in those studies and, on successful completion of that work, will be advanced to the medical or dental phase of the program.

Assignment to training in medicine and dentistry in the Army Specialized Training Program for the remainder of the year will be made from among enlisted men who prior to April 1 have been accepted for 1944 classes in contracting medical and dental schools.

Civilians now in medical or dental schools and those who have been accepted for a 1944 class in an accredited medical or dental school but who did not receive a call for induction prior to March 1 will not be assigned for Army Specialized Training Program training in medicine or dentistry.

Selection for preprofessional and subsequent professional training in medicine and dentistry will be restricted to soldiers who have completed their basic military training and have accomplished one of the following:

1. Passed an aptitude test for medical profession on successful completion of term 2 or term 3 in the Army Specialized Training Reserve Program.

2. Received a satisfactory score in the Army-Navy (A-12, V-12) College Qualifying Test (men in this group must have satisfactorily completed at least a year of premedical or pre-dental studies as civilians).

Priority will be given in the order as outlined. Any additional vacancies may be filled by soldiers selected on the basis of their proved abilities and academic background.

WARTIME GRADUATE MEDICAL MEETINGS

Additional subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

At Woodrow Wilson General Hospital, Staunton, Va.: Psychosomatic Medicine, Dr. O. B. Darden, March 30.

At Camp Pickett, Virginia: Physical Therapy in War Wounded, Major Ben L. Boynton, March 29.

At Ashford General Hospital, White Sulphur Springs, W. Va.: Shock, Burns and Fluid Balance (lecture, surgical ward rounds and clinical demonstrations), Dr. Alfred Blalock, March 27.

At Fort Eustis, Virginia: Recent Advances in Cardiovascular Disease, Dr. William B. Porter, March 30.

At Newton D. Baker General Hospital, Martinsburg, W. Va.: Drug Allergies, Dr. Leslie N. Gay, March 27.

METHYL BROMIDE PLACED
UNDER ALLOCATION

The War Production Board recently announced that methyl bromide, commonly used as an insecticide, has been placed under allocation, effective March 1, by amending Miscellaneous Chemicals Order M-340 to include it. The maximum monthly small order exemption is fixed at 10 pounds. No other deliveries may be made without specific authorization.

PRISONER OF WAR MAIL

A directive has been issued that letters or postal cards addressed to American prisoners of war in German camps should be placed by the sender in an outer unsealed envelop, addressed simply "Postmaster—Prisoner of War Mail." The inner envelop or card should be addressed in accord with the directions previously given. The letter or card may then be dropped in a mail box without postage. When collected by a postman the outer envelop will be removed by the Post Office and the letter or card will be sent, without postmarking, to New York for censorship, or the letter or card may be given to a post office clerk, without the outer envelop, and the mail will be forwarded to New York.

The sole purpose of this procedure is to avoid placing postmarks that will be objectionable to German authorities—postmarks such as "V for Victory" and "Buy War Saving Stamps and Bonds." Air mail letters must not have stamps marked with slogans or patriotic ideas, nor must objectionable endorsements be placed on the wrappers or cartons of next of kin parcels. The War Shipping Administration has announced that the American Red Cross has purchased the S. S. *Spokane*, a freighter, to be used for carrying relief parcels to Americans who are in German prison camps.

VITAMIN A PLACED UNDER
ALLOCATION

The War Production Board recently announced that vitamin A, which is sometimes used in overcoming night blindness, was placed under allocation for the first time. The action was taken to insure equitable distribution of the vitamin in the face of mounting demand. This increase in demand will exceed the volume of new supplies and make it necessary to draw on reserve. It was stated that this move would have no great effect on the public in the near future. Vitamin A occurs naturally in fish liver oils. Four synthetic vitamins already are under allocation. These are vitamin C, vitamin B₁, vitamin B₂, and nicotinic acid. Cod liver oil and tuna liver oil are not affected by the new order, No. M-373. Vitamin A in standard dosage forms or in food and feed compounds is also exempted.

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, March 4, p. 655)

INDIANA

Ball Memorial Hospital, Muncie. Capacity, 229; admissions, 6,506. Nellie G. Brown, Superintendent (3 interns, resident—pathology, resident—mixed, May 1).

MASSACHUSETTS

Beth Israel Hospital, Boston. Capacity, 215; admissions, 6,314. Charles F. Wilinsky, M.D., Executive Director (intern—pathology).

NEW YORK

Norwegian Lutheran Deaconesses' Home and Hospital, Brooklyn. Capacity, 162; admissions, 4,106. Rev. C. O. Pedersen, Superintendent (4 interns, 3 residents—October 1).

PENNSYLVANIA

Fitzgerald Mercy Hospital, Darby. Capacity, 191; admissions, 5,387. C. T. McCarthy, M.D., Medical Director (interns—October 1). St. Christopher's Hospital for Children, Philadelphia. Capacity, 45; admissions, 1,906. Mabel Barr, administrator (3 residents—pediatrics). St. Margaret Memorial Hospital, Pittsburgh. Capacity, 129; admissions, 2,191. Adele M. Poll, R.N., Superintendent (2 interns—October 1).

WISCONSIN

Luther Hospital, Eau Claire. Capacity, 146; admissions, 4,577. N. F. Hanshus, Superintendent (interns—March, July, November, and February—July).

ORGANIZATION SECTION

COMMITTEE ON POSTWAR MEDICAL SERVICE

The Committee on Postwar Medical Service met in Washington, D. C., on March 4. There were present Dr. Irvin Abell, Dr. F. G. Blake, Commander Edward L. Bortz, Dr. William B. Breed, Surg. Gen. Warren F. Draper, Dr. Walter F. Donaldson, Capt. W. E. Eaton, Dr. Morris Fishbein, Dr. Evarts Graham, Dr. Alan Gregg, Dr. C. M. Griffith, Dr. E. E. Irons, Dr. Roger I. Lee, Lieut. Col. Harold Lueth, Dr. James M. Mason, Dr. Walter W. Palmer, Dr. J. E. Paullin, Dr. G. M. Piersol, Brig. Gen. Fred W. Rankin and Dr. H. H. Shoulders.

QUESTIONNAIRE ON POSTWAR NEEDS

After the minutes of the previous meeting were approved, the chairman requested Dr. Lueth to discuss the problems involved in sending out questionnaires to physicians in the armed services on the subject of their expected needs on return to civilian life. Dr. Lueth discussed the sample questionnaire and the methods to be followed in phrasing its questions and interpreting the answers. It was moved, seconded and passed that a revised questionnaire be sent out at the earliest possible time to physicians in military service. The purpose of such a form of inquiry is of course to define more clearly the types of needs and requests of men on return from military service. From many points of view letters would be preferable to the mere answers to specific questions, but statistical treatment of letters is obviously difficult.

The possibility was suggested that the records of the Procurement and Assignment Services could be of value in postwar education or relocation problems. The secretary was instructed to inquire from the Honorable Paul V. McNutt in regard to his matter.

INFORMATION BUREAU AT HEADQUARTERS

Dr. Lee reported that the Board of Trustees of the American Medical Association was in favor of the creation, at staff headquarters of the Association, of an information service bureau,

though not of the ordinary placement type but rather a clearance agency for information on positions, opportunities and requests for physicians' services. Further planning will be needed as to the way in which such a service is to be organized.

Dr. Palmer stated that the principal need in further training will be related to the creation of additional places for assistant residents and residents in hospitals, including hospitals not now having such posts. The following motion was passed: It is of importance to the general welfare that an increased number of assistant residencies and residencies in hospitals (including hospitals now possessing such posts) be created for the education, training and adjustment of young physicians returning from military service to civilian practice.

It was also voted that the committee authorizes the chairman to appoint a subcommittee whose service will be offered to the Board of Trustees as available at any hearings on bill S. 1509 dealing with educational opportunities.

NEW MEMBERS FOR COMMITTEE

In the light of these motions and in connection with the committee's program as a whole, it was voted to invite representation on the committee from the Association of American Medical Colleges, the American Hospital Association, the Catholic Hospital Association, the Federation of State Licensing Boards, the Procurement and Assignment Services and the Advisory Board for Medical Specialties.

MEDICAL SUPPLIES

It was voted that inquiry be made of the proper authorities as to the eventual status of medical supplies at present under the Office of Civilian Defense.

It was voted that the next meeting of the committee be held Saturday, April 29, in New York.

OFFICIAL NOTES

MORE ELECTRICAL TRANSCRIPTIONS FOR RADIO PROGRAMS

The Bureau of Health Education announces the completion and immediate availability of a third series of electrically transcribed radio broadcasting records for local use by medical societies or in projects approved by the local medical society. This series consists of twelve broadcasts on six records. It is entitled *Dodging Contagious Diseases*.

Requests for these new transcriptions may be sent at once to the Bureau of Health Education of the American Medical Association, 535 North Dearborn Street, Chicago. There is no charge for the use of this material except the nominal cost of returning the records in the shipping container which is provided.

The records play ten minutes each, allowing five minutes of the usual fifteen minute radio schedule to be used locally for music or announcements by the local society.

Dodging Contagious Diseases is the third series of electrical transcriptions available. The first series, *American Medicine Serves the World at War*, and its continuation under the title *Medicine Serves America*, consists of eight broadcasts, additions being made month by month. The second series, *Before the Doctor Comes*, consists of sixteen broadcasts. All these series are available usually on short notice. From time to time, how-

ever, waiting lists exist. It is best to make reservations in advance.

A fourth series of transcriptions designed especially for broadcasts to and use in elementary schools is being developed under the title *Health Heroes and Hoboes*. This series will not be ready until the autumn term of school in 1944.

DOCTORS AT WAR

Radio broadcasts of *Doctors at War* by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at 4:30 p. m. Eastern war time (3:30 Central war time, 2:30 Mountain war time and 1:30 Pacific war time.)

The titles and guest speakers for the next three programs are as follows:

March 18. "You Must Help Win This War."
Speaker, Harold A. Vonachen, M.D., Medical Director, Caterpillar Tractor Company, Peoria, Ill.

March 25. "Our Blood For Our Boys."
Speaker, G. Cauby Robinson, M.D., National Director, Blood Donor Service, American Red Cross, Washington, D. C.

April 1. "White Reaper."
Speaker to be announced.

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION

Kentucky

Bill Introduced.—H. 362 proposes to enact an entirely new pharmacy practice act. Among other things this bill, as it was amended in the House March 6, proposes to prohibit the sale at retail of aminopyrine, barbituric acid, cinchophen, dinitrophenol, sulfanilamide, thyroid or their derivatives except on the written prescription of a licensed physician, dentist or veterinarian.

Mississippi

Bill Enacted.—S. 84, to amend the uniform narcotic drug act, was approved by the governor February 22. The new law so defines narcotic drug as to include isonipecaïne, which is defined as "the substance identified chemically as 1-methyl-4-phenyl-piperidine-4-carboxylic acid ethyl ester, or any salt thereof by whatever trade name identified."

Bills Introduced.—S. 324 proposes (1) to change the name of the South Mississippi State Charity Hospital to Laurel Community Hospital, (2) to provide for the control and management of that hospital by a board of trustees and (3) to permit certain portions of the hospital to be available for pay patients. S. 332 and H. 691 propose to authorize the boards of supervisors of Tate, DeSoto and Marshall counties to establish and operate a joint hospital. H. 668 proposes to prohibit any place serving or preparing food for human consumption from employing any food handler therein who does not possess a certificate from an appropriate public health authority that he or she has been examined and found free from venereal disease. H. 701 proposes to authorize the board of supervisors of Madison County to expend not more than \$100 on each needy maternity case. H. 708 proposes to appropriate \$655,380 to defray the expenses of the state board of health for the period beginning July 1, 1944 and ending June 30, 1946. H. 710 proposes to appropriate \$150,000 to defray the expenses of the state board of health in conducting a program of eradication and control of venereal diseases for the period beginning July 1, 1944 and ending June 30, 1946. H. 763 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a certificate from a licensed physician, based on physical and laboratory examination, that the party is free from venereal disease.

New York

Bills Introduced.—S. 1336 and A. 1678, to amend the laws relating to the practice of medicine, propose that the examination required for a license to practice medicine shall be dispensed with in the case of any applicant who has not previously taken and failed such examination, who meets all the requirements of law and who subsequent to Dec. 7, 1941 and for at least twelve consecutive months has served in and has been

honorably discharged from the medical corps of any branch of the armed forces. S. 657 and A. 1537 propose to make it a felony for a person to prescribe, supply or administer to a woman or advise or cause a woman to take any substance or to use or cause to be used any instrument or other means with intent to producing an abortion other than a therapeutic abortion. A therapeutic abortion is defined in the bill as "the artificial interruption of an intrauterine pregnancy before the period of viability (up to twenty-eight weeks of gestation) is reached, where the continuance of such pregnancy would jeopardize the life of the woman or so aggravate the physical or mental disease from which she suffers as seriously to impair her health or threaten her life. It may be performed only by a physician duly licensed in the state of New York and only in a hospital recognized by the department of social welfare of New York state or the department of health of New York state or approved by the American College of Surgeons and/or the American Medical Association, after written opinions as to its necessity have been obtained from two competent, qualified and recognized consultants in the respective specialties involved, which said written opinions shall be incorporated in the records of the hospital." A. 1594 proposes to prohibit the practice of x-ray diagnosis, x-ray therapy or radium therapy, except by licensed physicians, dentists or chiropodists. "X-ray diagnosis," according to the bill, "means that method of medical practice in which demonstration and examination of the normal and abnormal structures, parts or functions of the human body are made by use of x-rays, and any person who holds himself out to diagnose or able to make or makes any interpretation or explanation by word of mouth, writing or otherwise of the meaning of a fluoroscopic or registered shadow or shadows of any part of the human body made by the use of x-rays, and also the use of x-rays or radium for the treatment of any human ailment shall be deemed to be engaged in the practice of medicine within the meaning of this article." A. 1930, to amend the uniform narcotic drug act, proposes so to define narcotic drug as to include isonipecaïne, which is defined in the bill as "the substance identified chemically as 1-methyl-4-phenyl-piperidine-4-carboxylic acid ethyl ester, or any salt thereof by whatever trade name identified." A. 1826, to amend the laws relating to the practice of medicine, propose to make it a cause for revocation of a license for the physician concerned to participate in the division, transference, assignment, rebating, splitting or refunding of his fee for medical care.

South Carolina

Bill Enacted.—H. 945, to amend the uniform narcotic drug act, was approved by the governor March 4. The new law so defines narcotic drug as to include isonipecaïne, which is defined as "the substance identified chemically as 1-methyl-4-phenyl-piperidine-4-carboxylic acid ethyl ester, or any salt thereof by whatever trade name identified."

WOMAN'S AUXILIARY

Colorado

About 700 service men were entertained by the Denver County auxiliary recently at a buffet supper at the Service Men's Center.

The Pueblo County auxiliary and the Medical Auxiliary of Northeastern Colorado sewed for the Red Cross recently.

New Jersey

The year's project of Essex County is child welfare. The auxiliary gets in touch with nursing mothers who have an excess of milk, obtains this excess milk and sees that it reaches Coit Memorial Hospital, where it is processed and held in the milk bank until needed.

The Gloucester County auxiliary has made each member responsible for at least two *Hygia* subscriptions. Profits from subscriptions will be used to cover expenses of the reciprocity tea and for the annual donation to the Red Cross.

Hudson County auxiliary is making a collection of recipes to be published in a book and sold for the Benevolent Fund.

Mercer County auxiliary was hostess in January to the Woman's Auxiliary to the Medical Society of New Jersey.

West Virginia

At a recent meeting of the Woman's Auxiliary to the McDowell County Medical Society, Dr. C. W. Vick spoke on "History of Medicine in McDowell County." Books, magazines and games were sent to the Ashford General Hospital at White Sulphur Springs.

The Raleigh County auxiliary met in November. Mrs. Ross P. Daniel, president, discussed the Wagner-Murray-Dingell bill.

A luncheon meeting of the Woman's Auxiliary to the Kanawha Medical Society was held at the Charleston Woman's Club in November. Mrs. A. A. Shawkey reviewed "The Story of Doctor Wassell." The Christmas party was held at the home of Mrs. A. C. Wilson.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—In a resolution sent to Governor Sparks the Jefferson County Medical Society has recommended the appointment of Dr. James S. McLester, Birmingham, for a post on the medical advisory board of the University of Alabama Medical School to be established in Birmingham.

State Medical Meeting.—The Medical Association of the State of Alabama will conduct its annual session at the Whitley Hotel, Montgomery, April 18-20, under the presidency of Dr. Fred W. Wilkerson, Montgomery, and with the Montgomery County Medical Society acting as host. Out of state speakers on the program will include:

Lieut. Col. Walter O. Klingman, M. C., A. U. S., Psychiatric Problems in Flying Personnel.

Dr. John E. Walker, Columbus, Ga., The Significance of the Wide S Wave Pattern of the Electrocardiogram.

Dr. Paul W. Austin, West Point, Ga., The Value of the Preemployment Examination in an Industrial Health Program.

Dr. Arthur Neal Owens, New Orleans, Some Recent Trends in the Advancement of Plastic Surgery.

Dr. Francis E. Le Jeune, New Orleans, The Prognosis and Treatment of Cancer of the Larynx.

Dr. Randolph Lyons, New Orleans, The Schemm Treatment of Chronic Heart Failure with Edema: Report of Illustrative Case.

Dr. Morris Fishbein, Editor, THE JOURNAL, Planning for Postwar Medical Services.

Dr. Cobb Pilcher, Nashville, Tenn., The Treatment of Cranio cerebral Wounds.

The Jerome Cochran Lecture will be delivered by Dr. Tinsley R. Harrison, dean of the Southwestern Medical College of the Southwestern Medical Foundation, Dallas, Texas, on "The Value and Limitations of Laboratory Tests in the Practice of Medicine."

COLORADO

Dr. Lull Resigns from State Board.—Dr. Lynn J. Lull, Denver, has resigned as director of the venereal disease control division of the Colorado State Division of Public Health. Newspapers report that he will take over a similar position in the Idaho State Board of Health at Boise.

CONNECTICUT

Psittacosis.—The Hooper Foundation for Medical Research of the University of California, San Francisco, recently confirmed the diagnosis of psittacosis in 2 parakeets that had been shipped illegally into Connecticut from Texas by railway express. One of the birds died soon after arrival. The parakeets had been intercepted in Connecticut before they had been delivered to the mother of a soldier stationed in Texas. It is reported that during 1943, preceding the arrival of these infected birds, four other illegal shipments of birds had been reported. Three had been made from Texas and the other from the District of Columbia. In an effort to preclude further illegal shipments of parakeets by its facility, the railway express agency has recently issued a traffic department circular giving detailed information to their agents with regard to the legal requirements for the acceptance of birds of the psittacosis family for shipment from one state to another.

DISTRICT OF COLUMBIA

Board of Visitors.—The District commissioners have appointed a board of visitors for the municipal hospitals, Washington. According to *Medical Annals of the District of Columbia* a lay board of visitors can be of great value to an administrator by bringing the layman's point of view and acting as friendly advisers. *Medical Annals* further states that this is a step that should redound to the benefit of the public hospitals of the District.

GEORGIA

Convicts to Serve in Malaria Tests.—More than 200 inmates of the federal penitentiary in Atlanta have volunteered to serve as human "guinea pigs" for experiments seeking a malaria remedy more potent than quinine or atabrine. Newspapers announced that experiments would be conducted in cooperation with the National Research Council acting for the Office of Scientific Research and Development and its committee on medical research. The study will be under the supervision of the U. S. Public Health Service and will be integrated with similar undertakings at a number of civilian

institutions. At the Federal Reformatory, El Reno, Okla., 300 inmates are at present voluntarily taking gas gangrene toxoid inoculations. John T. Wright, A. Surg., U. S. Public Health Service, is in charge, the results of which have not yet been announced. In a newspaper report concerning the project at New Jersey State Prison last May, when 317 inmates volunteered in a test of a vaccine to be used against epidemic encephalitis, it was stated that there was a mild reaction in about 3 per cent of the cases. Only one volunteer was seriously affected; he almost died but recovered. The New Jersey study was under the supervision of Dr. Robert Ward, New Haven, Conn., for the U. S. Army.

IOWA

Personal.—Dr. Frank O. Kershner, Clinton, has retired from active practice on account of ill health.—Dr. Willis E. Brown, assistant professor of obstetrics and gynecology, University of Nebraska College of Medicine, Omaha, has been appointed to a similar position at the State University of Iowa College of Medicine, Iowa City.

State Medical Meeting.—The ninety-third annual session of the Iowa State Medical Society will be held at the Hotel Fort Des Moines, April 20-21, under the presidency of Dr. Lee R. Woodward, Mason City. The guest speakers will include:

Dr. Anton J. Carlson, Chicago, Physiologic Aspects of Cardiac Disease.

Dr. William N. Hahn, Omaha, Procedures Following Some of the More Frequent Eye Injuries.

Dr. Clarence D. Selby, Detroit, A Postwar Industrial Medical Program.

Lieut. Col. Malcolm J. Ferrell, M. R. C., Developments in Military Neuropsychiatry.

Dr. Walter H. Judd, Washington, D. C., Postwar Planning.

Dr. Norman F. Miller, Ann Arbor, Mich., Toxemias of Late Pregnancy.

Dr. Alfred W. Adson, Rochester, Minn., The Activities of the Council on Medical Service and Public Relations and the Responsibilities of Individual Physicians.

The State Society of Iowa Medical Women and the American Medical Women's Association, Branch 19, will meet April 20. The Woman's Auxiliary to the state medical society will hold its fifteenth annual session at the Hotel Kirkwood, Des Moines, April 20-21.

KANSAS

Executive Secretary Resigns.—Mr. Robert Brooks, Topeka, has resigned as executive secretary of the Kansas Medical Society, effective February 1. He had held the position since October 1942 after Mr. Clarence Munns was granted leave of absence to enter military service. Mrs. Margaret Foster, secretary in the executive office of the state society, has been named acting executive secretary.

KENTUCKY

Changes in Health Officers.—Dr. James A. Campbell, health director of Scott County, has been transferred to a similar position in Mason County. Dr. George M. Jewell, Paris, health director of Bourbon County, has been assigned to Scott County for two days each week.

MASSACHUSETTS

Health Department Opens Veterans' Clinic.—The state department of mental health has opened an outpatient clinic for veterans of World War II from Essex County. The clinic is in charge of Dr. Clarence A. Bonner, medical superintendent of the Danvers State Hospital, Hathorne, and is interested in men and women who have been discharged from the armed forces or rejected from their draft boards because of such symptoms as nervous heart or nervous stomach, dizziness, headaches, fainting spells, fits and seizures, irritability, outbursts of temper, easy fatigability and poor memory. Rehabilitation efforts will be instituted to help these persons become readjusted in the community and in industry.

MICHIGAN

Society News.—The Wayne County Medical Society and the Michigan Society of Obstetricians and Gynecologists were addressed in joint session March 6 by Dr. M. Edward Davis, Chicago, on "Modern Management of the Third Stage and Its Complications."—On January 12 Dr. Roy D. McClure and the surgical staff of the Henry Ford Hospital, Detroit, entertained the members of the Flint Academy of Surgery at a scientific meeting, luncheon and surgical clinic.

Dr. De Kleine Named State Health Commissioner.—Dr. William De Kleine, for many years director of medical and health service of the American Red Cross, on February 18 has been named state health commissioner for Michigan. The appointment would be for the remaining three year term of the late Dr. Henry Allen Moyer, if confirmed by the senate, newspapers report. Dr. De Kleine graduated at Northwestern

University Medical School, Chicago, in 1906 and received his master of science degree at the University of Michigan School of Public Health, Ann Arbor, in 1915. For a number of years he practiced medicine in Grand Haven, subsequently throughout his career maintaining his residence there. He served in various capacities on the state board of health. In 1927 he became associated with the American Red Cross during the Mississippi Valley flood and the following year was named director of medical and health service. He resigned in 1941. He once served as president of the Michigan Tuberculosis Association and of the Michigan Public Health Association.

MINNESOTA

Dr. Hansen Named Director of Ophthalmology Division.—Dr. Erling W. Hansen, clinical assistant professor of ophthalmology at the University of Minnesota Medical School, Minneapolis, has been appointed clinical professor and director of the division of ophthalmology at the university.

NEW JERSEY

The Harrison Martland Lecture.—The ninth annual Harrison S. Martland Lecture will be given by Dr. Otto Loewi, research professor of pharmacology, New York University College of Medicine, March 22, at the Academy of Medicine of Northern New Jersey, Newark. This annual lecture is given in honor of Dr. Martland by the Essex County Anatomical and Pathological Society.

New Health Exhibits.—Seven new cases of material which continues the story of the Human Body, How It Works, were placed on exhibition in the Newark Museum in the science department, March 7. The addition to the museum's display was made possible by a gift of the late Louis Bamberger, honorary president of the museum. In the planning of the exhibits a special committee was appointed by the Academy of Medicine of Northern New Jersey, of which Dr. Royal A. Schaff, Newark, is chairman. The group includes displays on How We Hear, How We Breathe, Of These We Are Made, Life Continues, a case on posture and one with questions and answers relating to the skin. Two cases related to the ear show the manner in which sound travels from the outer ear to the auditory nerve, with a set of chimes indicating what happens when the nerve impulses reach the brain.

NEW YORK

Veterans' Loan Fund.—The Westchester Medical Veterans' Loan Fund has been set up by members of the Medical Society of the County of Westchester. The fund will be available for returning members of the service to aid in reestablishing their private practice or serve other needs which may be required.

Graduate Lecture.—On April 19 Dr. Harvey B. Matthews, clinical professor of obstetrics and gynecology, Long Island College of Medicine, Brooklyn, will address the Saranac Lake Medical Society on "Forceps Delivery: Indications, Dangers and Accomplishment." The lecture is sponsored cooperatively by the state medical society and the state department of health.

Health Department Divisions Moved.—The offices of several units of the state department of health in Albany were moved recently. The office of medical administration, the division of maternity, infancy and child hygiene and the division of orthopedics are now located on the eighth floor of the Bond Building, 74-76 State Street. The division of cancer control and the division of public health education have quarters in the New York State Teachers Association Building, 152 Washington Avenue. The bureau of narcotic control has been moved to the fifteenth floor of the State Office Building. The work of the bureau of pneumonia control, formerly under the direction of the assistant commissioner for medical administration, has been reintegrated with that of the division of communicable diseases and space allotted to its staff on the fifteenth floor of the State Office Building.

New York City

Health Topics at Safety Meeting.—At the fifteenth annual safety convention and exposition of the Greater New York Safety Council, in the Hotel Pennsylvania, March 28-30, sessions will be devoted to occupational diseases and industrial nursing, women workers and eye protection.

Physiologist Dies.—Helen Copeland Coombs, Ph.D., instructor in physiology at Brooklyn College, Brooklyn, died March 4, aged 52. Dr. Coombs had done special research on the nervous mechanism of respiration, cerebral anemia, cardiovascular nervous mechanism, neurophysiology and pharmacology and relation of calcium and phosphorus metabolism to the nervous system.

Physician Sentenced for Abortion.—Dr. Alice M. N. Chairman was sentenced to a year in the penitentiary on February 23 by Judge Jacob Gould Schurman Jr. in general sessions for performing an abortion on an 18 year old woman, according to the New York Times. The Times also stated that Dr. Chairman was practicing medicine without a license, hers having been revoked in 1940.

First Lisa Award.—The Society of the Alumni of City (Charity) Hospital announces the presentation of the first James R. Lisa Award to Lieut. Chauncey L. Royster, M. C., A. U. S. Lieutenant Royster received the award for his work on "The Cardiac Findings in Syphilis Combined with Hypertension, in the Absence of Aortic Regurgitation." The Lisa Award was established by the Alumni Society of the City Hospital to recognize work in research medicine done in the laboratories of the hospital under Dr. Lisa's direction, the award to be made by Dr. Lisa at appropriate times to the worker deemed by him to be worthy of it. The award consists of a medallion and an honorarium of several hundred dollars (THE JOURNAL, Jan. 23, 1943, page 271). Lieut. Royster graduated at Cornell University Medical College in 1935 and served his internship and residency at the city hospital.

Center in Tropical Medicine to Be Developed at Columbia.—Plans to establish a world training center in tropical medicine at the Columbia University College of Physicians and Surgeons were announced to the press February 26 by Dr. Harry S. Mustard, professor of public health practice and director of the DeLamar Institute of Public Health at Columbia. The plans call for new building facilities, a greatly expanded personnel and additional laboratories and equipment. Recently the university established a department of tropical medicine in charge of Dr. Harold W. Brown as professor of parasitology (THE JOURNAL, Nov. 6, 1943, p. 647). The entire program of tropical medicine at Columbia will be under the direction of the DeLamar Institute of Public Health and has been made possible by a grant of \$150,000 from the Josiah Macy Jr. Foundation (THE JOURNAL, Jan. 23, 1943, p. 271). In addition the John and Mary R. Markle Foundation has given a sum for research in filariasis.

Welfare Council to Be Reorganized.—The Welfare Council of New York City, a federation of 700 local health and welfare agencies, will be reorganized to carry out more effectively its purpose of "contributing to the strategic employment of all resources existing or projected to meet present and foreseeable welfare and health needs of the City of New York." The action stemmed from the approval of a report on a recently completed eighteen months survey. Principal changes in the new plan affect representation in the directing bodies of the Welfare Council, and the plan calls for the appointment of a long range planning committee whose composition will insure "broad consideration of problems that cross the lines arbitrarily separating the fields of the other standing committees." The Welfare Council of New York City was founded in 1925. Its present administrative structure consists of a board of directors of 87 persons, both lay and professional, and an executive committee of 39. Both figures include certain ex officio members. The new plan calls for the reduction of these numbers by more than half.

Experimental Program on Industrial Health Education.—At a dinner on February 28 in the Hotel St. George, Brooklyn, the Fort Greene industrial health committee launched a demonstration program on health education for industrial workers in the Fort Greene District of Brooklyn. The project will be run for one year as a cooperative undertaking of management, employee groups, the New York City Health Department, the medical profession and a number of voluntary health agencies. It is anticipated that about 150,000 persons employed in the area will be reached by the drive to reduce preventable accidents, illness and resultant absenteeism. Headquarters for the project are in the Fort Greene Health Center of the New York City Health Department, 295 Flatbush Avenue Extension, Brooklyn. A panel discussion featured the dinner meeting on "Here's to Your Health" and was participated in by Reginald E. Gillmor, president of the Sperry Gyroscope Company; Erval R. Coffey, assistant surgeon general, U. S. Public Health Service; Dr. Victor G. Heiser, consultant on industrial health, National Association of Manufacturers; Dr. Leo S. Schwartz, Brooklyn, president, Medical Society of the County of Kings, and Dr. Jacob H. Landes, Brooklyn, health officer of the Fort Greene District. Mr. Gillmor and Louis Hollander, manager of the other New York Joint Board, Amalgamated Clothing Workers of America, are co-chairmen in the program. "Here's to Your Health" is also the title of an educational bulletin, the first issue of which appeared March 1.

OHIO

The Hanna Lecture.—Francis J. W. Roughton, Ph.D., lecturer in physiology, Cambridge University, England, will deliver the forty-ninth Hanna Lecture before the Academy of Medicine of Cleveland, April 12, at the Institute of Pathology, 2085 Adelbert Road. His subject will be "Some Recent Work on the Respiratory Chemistry of the Blood."

Diabetes in Children.—The Council on Diabetes of the Public Health Federation, Cincinnati, in cooperation with various health departments, is asking that physicians report to the secretary of the council the names and addresses of diabetic patients who are 18 years of age or younger. The council proposes to assist school nurses in their effort to have pertinent information with reference to these children on pupils' health cards. Names and addresses should be sent to Mrs. Joseph N. Gantz, secretary, Council on Diabetes, 312 West Ninth Street, Cincinnati 2.

Postgraduate Assembly.—The Mahoning County Medical Society will hold its sixteenth annual postgraduate assembly at the Pick-Ohio Hotel, Youngstown, April 19. At the afternoon session speakers will be Drs. William D. Collier, Youngstown, on "Clinical Problems Concerned with Blood Incompatibilities"; James Ross Veal, Washington, D. C., "Surgery of Thrombosis of the Peripheral Veins," and Edgar C. Baker, Youngstown, "Venography of the Lower Extremity." A dinner session will be addressed by Dr. Veal on "Acute Obstruction of the Small Intestines" and Dr. Eugene R. Whitmore, Washington, "Postwar Problems of Tropical Diseases in Civilian Practice."

New Appointments Under Research Expansion Program.—Fred W. Oberst, Ph.D., Lexington, Ky., has been placed in charge in the newly organized biochemistry department at the William S. Merrell Company, Cincinnati, and Harold W. Werner, Ph.D., has been named head of the department of pharmacology. The new department of biochemistry is located in the Cincinnati office of the Merrell Company and is one of the various units that comprise the research laboratories. Dr. Oberst has been engaged in biologic research on narcotics and drug addiction at the U. S. Public Health Service Hospital, Lexington, and Dr. Werner has been assistant professor of physiology and pharmacology at the University of North Dakota School of Medicine, Grand Forks, and pharmacologist at the National Institute of Health, Bethesda, Md.

PENNSYLVANIA

Society News.—Dr. George P. Guilbor and Mr. Austin B. Belgard, Chicago, and Dr. Chevalier L. Jackson, Philadelphia, will be the guest speakers at a meeting of the Reading Eye, Ear, Nose and Throat Society in Reading, April 19. The program will include clinics, conferences on the conservation of hearing and optical centers and four papers on motor disturbances (diagnosis, use of prisms, use of atropine, surgery). A lecture on "The Bronchial Tree" will also be given.

Philadelphia

Annual Health Institute.—The Woman's Auxiliary of the Philadelphia County Medical Society will sponsor its fourteenth annual health institute, April 11, at the Philadelphia County Medical Society. "Health Trends" will be the theme of the program, which will be presented by:

Dr. David A. Cooper, Mass X-Ray in Tuberculosis Case Findings.
Dr. Hubley R. Owen, Plans for the Medical Division of the Board of Education.
Dr. George Morris Piersol, Plans for New Developments in Physical Therapy.
Miss Theresa I. Lynch, Trends in Hospital Nursing.
Miss Mary L. Poole, The Functions of a Social Service Department in the Hospital.
Dr. Franklin D. Murphy, Dramatic Results from Modern Chemotherapy.
Capt. Jesse W. Allen (MC), U. S. Navy, Movies: Latest Authentic Eastern War Pictures.

Copyright of Pharmaceutical Textbook Transferred to College of Pharmacy.—A copyright of the textbook "Remington's Practice of Pharmacy" was recently transferred to the corporate body of the Philadelphia College of Pharmacy and Science as a memorial to the late Joseph P. Remington, dean of the college. The ownership of the copyright has been vested in the heirs of the Remington estate for decades. The gift was presented officially by Rev. William P. Remington, bishop of Oregon, acting in behalf of the living legatees. In accepting the gift the board of trustees of the college at once formulated plans whereby its revision would be undertaken so as to continue it as a widely accepted pharmaceutical reference authority and textbook. Ernest Fullerton Cook, Pharm.D., for many years assistant to Dean Remington, has been appointed editor for the current revision.

RHODE ISLAND

Personal.—Dr. Reuben C. Bates, Providence, has been elected a member of the governing council of the American Association of Medical Milk Commissions. Dr. Bates has served for many years as secretary of the Medical Milk Commission of the Providence Medical Association. —Comdr. William A. Stoops (MC), U. S. Naval Reserve, has been appointed president of the Newport Board of Health, and Dr. James C. Callahan was appointed secretary and a member of the board for a five year term. Dr. Callahan succeeds Dr. Samuel Adelson.

TEXAS

Graduate Assembly of Negro Physicians.—The eighth annual postgraduate assembly of Negro physicians in Texas was held at Prairie View State Normal and Industrial College, Prairie View, March 6-8. The assembly was sponsored by the State Medical Association of Texas, Lone Star State Medical, Dental and Pharmaceutical Association, National Tuberculosis Association, Texas Tuberculosis Association, Texas State Board of Health and the Prairie View State Normal and Industrial College. Dr. Arild E. Hansen, Galveston, addressed a public health meeting Tuesday evening on "The Practicing Physician's Responsibilities in the Problem of Child Health." Other speakers on the program included:

Dr. Edward L. Turner, Nashville, Tenn., Tropical Diseases as They May Affect Medical Practice in the United States.
Dr. Clarence Leon Wilson, Chicago, Some Misfortunes in Anesthesia in Labor.
Dr. William Roderick Brown Jr., Pittsburgh, Correlation of Criteria for Early Diagnosis in Pulmonary Tuberculosis.
Dr. Shirley S. Bowen, Houston, Therapeutic Principles in the Treatment of Syphilis.
Dr. Frank H. Lancaster, Houston, The Use of Sulfa Drugs in Children.
Dr. Ludwik Anigstein, Galveston, The Dysenteries.
Dr. John Potts, Fort Worth, Chest Pains as Diagnostic Leads and Diagnostic Factors.
Dr. Theodore K. Lawless, Chicago, The Clinical Manifestations of Syphilis.
James L. Tenney, Austin, administrative assistant, maternal and child health bureau, Texas State Board of Health, The Program of the U. S. Children's Bureau for Emergency Care of Wives and Infants of Servicemen.

WEST VIRGINIA

License Restored.—The license of Dr. Elmer G. Kesler, Williamsburg, was probationally restored recently with the provision that he would not apply for a narcotic permit or use narcotics or alcohol in any form. He was also directed to report to the public health council at quarterly intervals.

GENERAL

Dietetic Association Changes Date of Meeting.—The annual meeting of the American Dietetic Association will be held at the Palmer House, Chicago, October 25-27, instead of at the Stevens Hotel, October 17-19 as was previously announced (THE JOURNAL, February 26, p. 587).

Examinations in Ophthalmology.—The American Board of Ophthalmology announces that future examinations will be held in New York June 2, 3 and 5 and in Chicago October 5-7. The address of the board has been changed from P. O. Box 1940, Portland, Maine, to 704 Congress Street, Portland.

Society News.—The American Association for the Surgery of Trauma will hold its annual meeting at the Edgewater Beach Hotel, Chicago, June 9-10. Dr. Gordon M. Morrison, 520 Commonwealth Avenue, Boston, is the secretary. —The Catholic Hospital Association of the United States and Canada will conduct its twenty-ninth annual convention and second wartime conference at the Kiel Municipal Auditorium, St. Louis, May 21-26.

Dr. Winslow Named Editor of Public Health Journal.—Charles-Edward A. Winslow, Dr.P.H., Anna M. R. Lauder professor of public health, Yale University School of Medicine, New Haven, has been appointed editor of the *American Journal of Public Health*, succeeding Dr. Harry S. Mustard, New York. Dr. Winslow will assume his new position with the April issue. Dr. Winslow was president of the American Public Health Association in 1926 and in 1942 received a certificate for forty years of continuous membership and the Sedgwick Memorial Medal for distinguished service to public health.

Postgraduate Courses of College of Physicians.—The American College of Physicians has arranged a group of postgraduate courses. The first will be conducted April 10-15 at the University of Michigan Medical School and University Hospital, Ann Arbor, and will be devoted to general medicine. Members of the faculty at the medical school will cooperate in the instruction. "Clinical Medicine with Special Emphasis

upon the Hematologic Viewpoint" will be the theme of the second course, April 17-22, at the Ohio State University College of Medicine, Columbus, with members of the school faculty cooperating. The third course will be devoted to selected phases of internal medicine and will be conducted at the medical clinic at the Massachusetts General Hospital, Boston. Members of the faculty of Harvard Medical School will direct the instruction.

Conference of State and Provincial Health Authorities.—The fifty-ninth annual Conference of State and Provincial Health Authorities of North America will be held in Washington, D. C., March 22, in the District Medical Society Building, under the presidency of Dr. J. Lynn Mahaffey, Trenton, N. J. Among the speakers will be:

Dr. Stanley H. Osborn, Hartford, Conn., Dr. John T. Phair, Toronto, and James G. Townsend, medical director, U. S. Public Health Service, Industrial Health.

Dr. Kendall Emerson, New York, Postwar Problems of Tuberculosis.

Dr. Haven Emerson, New York, Local Health Units.

Dr. Wilton L. Halverson, Los Angeles, Training of Duration Public Health Personnel.

A round table discussion will be held on public health nutrition problems with Dr. Walter E. Wilkins, Raleigh, N. C., of the War Food Administration, as chairman.

Prizes for Research in Allergy.—Two annual awards have been established under the sponsorship of the American Academy of Allergy, effective January 1. One is the Abbott Award, which will consist of an annual prize of \$200 established by the Abbott Laboratories of Chicago, to be granted annually for the most important advancement in the field of allergy or for the development of a research problem on any phase of the subject. This prize will be considered for both members and nonmembers of the academy. The second award, to be known as the Secretary's Prize, is a medal to be given annually to a member of the academy for "the most outstanding achievement of the year in the general field of allergy." The American Academy of Allergy was formed recently when the Society for the Study of Asthma and Allied Conditions and the American Association for the Study of Allergy merged (THE JOURNAL, Dec. 25, 1943, p. 1129).

State and Territorial Health Officers.—The forty-second annual conference of the Association of State and Territorial Health Officers with the U. S. Public Health Service and the U. S. Department of Labor Children's Bureau will be held at the auditorium of the Medical Society of the District of Columbia, Washington, March 20-23, under the presidency of Dr. Irl C. Riggan, Richmond, Va. Among the speakers on the program will be:

Dr. G. Foard McGinnes, Washington, D. C., Utilization of Blood By-Products.

Thomas Parran, Surgeon General, U. S. Public Health Service, The State of the Nation's Health.

Hon. Paul V. McNutt, administrator, Federal Security Agency, Special Health Problems Affecting Manpower.

Joseph W. Mountin, medical director, U. S. Public Health Service, chief, states relations division, Present Status of Federal Legislation and Appropriations.

Stanley B. Freeborn, senior sanitarian, U. S. Public Health Service, The Eradication of Endemic Malaria.

Clifford R. Eskey, medical director in charge, typhus fever control section, The Increasing Importance of Endemic Typhus Fever.

Rolla E. Dyer, assistant surgeon general, U. S. Public Health Service, Exotic Diseases with Which Health Officers May be Concerned.

Features of the program will be a conference with the Children's Bureau with Miss Katharine F. Lenroot, chief of the bureau, presiding as chairman. The theme will be "Aspects of the Maternal and Child Health Program" with Drs. Edwin F. Daily and Sarah S. Deitrick, Washington, D. C., as the speakers. Another conference with the bureau will be presided over by Dr. Martha M. Eliot, associate chief of the bureau, presiding, to discuss the "Crippled Children Program Report." Dr. Abram L. Van Horn, Washington, D. C., will present a report on the "Rheumatic Fever Program."

LATIN AMERICA

Health Activities in Latin America.—The Hospital Insurance Association of Puerto Rico, San Juan, has signed contracts with fifteen hospitals and clinics throughout the island to offer medical services and hospitalization to members of the Blue Cross plan recently established here. The subscriber will pay 75 cents a month per person and \$1.50 a family per month as the quota established by the association.

Health Improvements in Puerto Rico.—A program of public health improvements submitted by Dr. Antonio Fernos-Isern, San Juan, commissioner of health, to reduce mortality rates in Puerto Rico includes extension and improvement of sewerage systems for the towns of Arecibo, Adjuntas, Aibonito,

Coamo, Guaynabo, Isabela, Moca, Patillas, Quebradillas, Guanica, Jayuya, Naranjito, Villalba and Aguas Buenas, also improvements to sewerage systems in twenty-four more municipalities; extension and improvements of water supply systems in urban and rural areas, with an appropriation of \$320,000; construction of 10,000 latrines at a cost of \$1,200,000; construction of antituberculosis sanatoriums in Arecibo, Aguadilla, Humacao and Cayey; extension to the Antituberculosis Sanatorium in Aibonito, Rio Piedras, Ponce, Mayaguez; extension of the malaria control program with an appropriation of \$62,450, and extension of the second unit health systems in the rural areas of Puerto Rico.

FOREIGN

Free Health Service in Great Britain.—A White Paper was presented to Parliament February 17 proposing a comprehensive medical service for all persons, newspapers reported. The proposal seeks to make available for every one advice, treatment and care with the best available facilities regardless of the patient's ability to pay. According to the *New York Times*, this is the first postwar social program outlined by Sir William Beveridge to be developed and it is the first one to attain this stage under the guidance of Lord Woolton, minister of reconstruction. The annual cost to the nation is estimated to be 146 million pounds. The *New York Times* further states that there will be no debate on the scheme until midsummer at the earliest, since the government is eager to gain full reports from the medical profession, local authorities and others affected before drawing up a bill embracing the major proposals. It was stated that the object of the policy set forth in the White Paper is "to bring the country's full resources to bear on reducing ill health and promoting good health in all its citizens. The objectives are:

To insure that every one in the country, irrespective of means, age, sex or occupation, has an equal opportunity to benefit from the best and most up to date medical and allied services available.

To provide, therefore, for all who want it a comprehensive service covering every branch of medical and allied activity from the care of minor ailments to major medicine and surgery; to include the care of mental as well as physical health and all specialist services, for example tuberculosis, cancer, infectious diseases, maternity, fracture and orthopedic treatment.

To divorce care of health from questions of personal means or other factors irrelevant to it; to provide service free of charge and encourage a new attitude toward health—easier obtaining of advice and early promotion of good health rather than only the treatment of bad.

In a statement to the press, Lord Dawson, president of the British Medical Association, said the project was a genuine statesmanlike endeavor to meet an extremely difficult position. The statement continued:

Within its framework of objects and principles much remains to be worked out. There are many points to be clarified as, for example, the experimental character of the health centers, the relationship of the individual family doctor to the hospitals, the mode of appointment and distribution of consultants, the compensation for the loss of capital value in general practices, the machinery by which the public will intimate its desire to avail itself of the service in whole or in part, the future of voluntary hospitals and contributory schemes and, not the least important, the functions of the proposed central medical board.

The *Times* stated that the status of the individual doctor is inviting the widest comment. The *Times* quotes the *Manchester Guardian*: "Not only is the doctor free to take part in the scheme or not—free, if he does take part to practice alone or as a group member—free even to buy and sell public practice, he will also be free to treat for a fee as a private practitioner patients who could claim the same treatment from him without charge." It was stated that the White Paper recognized the necessity of protecting the patients but does not explain how this can be done without insisting that every doctor must choose between public and private practice. In commenting on the reaction of the British Medical Association, it was stated that the association has a real fear of a general clinical instruction being handed down "from on high" and that the medical profession will "fossilize" like civil service. It was stated that a full reply to the government will be made when the 15,000 medical men in the armed forces turn in their questionnaires on the subject.

CORRECTION

Thymectomy for Myasthenia Gravis.—In the current comment with this title in THE JOURNAL for February 26, page 579, appears the statement "This assumption is supported by the frequency of cellular hyperplasia in the thymus in neurasthenia." The word neurasthenia should obviously have been myasthenia.

Feb. 12, 1944.

The Artificial Limb Center at Roehampton

The little Surrey village of Roehampton has become famous as the greatest center in Britain for the manufacture and fitting of artificial limbs. The work began in the first world war, when of 41,050 men who lost a limb 26,262 were treated there and supplied with their first and, in many cases, their second limb. After the armistice the institution was extended to accommodate general surgical and medical patients from the Ministry of Pensions Hospital in London and patients with facial wounds from Queen Mary's Hospital, Sidcup, but it still remained primarily for the benefit of men who had lost limbs in war. In this country there are now fourteen centers for limb fitting, and all their surgeons have been trained at Roehampton. Here also most of the progress in design and manufacture has been made. Thanks largely to Roehampton the modern artificial limb is of light and simple construction, permitting leg movements scarcely distinguishable from the natural gait. This highly specialized craft has been so perfected that the time between amputation and return to more or less normal life is greatly reduced. Provision is also made for occupational therapy, with gymnasium and workshops, and for the patient's economic and recreational rehabilitation.

The work has now been extended to amputation patients among civilians, and in the present war many civilians who have lost limbs as a result of German bombs have been treated. Recently a still wider field has been inaugurated. The limb fitting center, with its demonstration theater and consultation rooms, has been extended and the factories have been enlarged. It is proposed further that Roehampton should be a center for teaching the doctors of allied nations, many of whom are in England, the methods of manufacturing and fitting artificial limbs, so that the experience gained at Roehampton may help cripples everywhere.

Improved Vital Statistics

The astonishing fact that vital statistics have improved during the greatest war ever waged by this country has been reported more than once in previous letters to THE JOURNAL. A big increase in births for the quarter ended last September 30 has just been published. A total of 169,348 live births was registered, representing a birth rate of 16.2 per thousand per annum—the highest third quarter since 1930. Also the infant mortality rate—40 per thousand live births—was the lowest quarterly rate ever recorded. During the first nine months of 1943 521,858 live births were registered, compared with 494,171 in the same period of 1942.

In the third quarter there was a substantial fall in the number of marriages. The total of 81,454 was the lowest for any third quarter since 1918, while the rate, 15.6 persons married per thousand of population, was the lowest for any period since 1917. This fall is explained as a consequence of the great increase in the number of marriages which followed the outbreak of war. The death rate for the third quarter was low: 9.4 per thousand of population.

Commenting on these figures the physiologist Sir Leonard Hill says that the record low infant mortality is especially good. He attributes it to the work of advisory clinics and other health services. The birth rate of 16.2 per thousand is not high enough, he stated, though it represents a movement in the right direction. A birth rate of over 19 per thousand is required to maintain our population.

The Future of Pharmacy

At a recent meeting of the Pharmaceutical Society Sir Henry Dale, president of the Royal Society, discussed the effect of new discoveries on the future of pharmacy. Old fashioned dispensing to individual prescriptions would doubtless linger for a time, he said, but it was inevitable that the preparation of remedies required by progressive therapeutics would eventually be entirely by scientific, large scale manufacture. The role of the individual pharmacist would become little more than an intelligent retail distribution of ready made, centrally standardized products, he thought.

Rarely under present conditions of domestic practice could the physician obtain for his patient, or the patient receive through his physician, all that science offered in such growing profusion for the understanding of his illness and its effective treatment, Sir Henry stated. Unless the practitioner was to become a mere "sorting machine" to secure the transfer to hospital of every patient requiring scientific attention, he said, general practice must acquire such an organization that the common laboratory facilities which any modern hospital afforded could be made accessible to any practitioner who knew how to use them. A great number of new laboratory centers with well trained men would then have to be a feature of any adequate scheme, it was pointed out, and the sphere of the pharmacist would be largely transferred from his pharmacy to large laboratories in hospitals.

German Brutality to Russian Prisoners

The *Times* recently reproduced from the *Adelaide Advertiser* the statements of Warrant Officer Ian Sabey, a member of the editorial staff of the *Advertiser*, who was recently repatriated after thirty-two months' imprisonment in Greece, Crete and Germany. He stated that British prisoners in Germany have been witnesses of the greatest cruelties and sadistic treatment of Russian prisoners. When the time comes for British prisoners to make charges, even their horrible experiences pale into insignificance beside those of the tortured and starved Russians whose bodies lie in great pits around their prison camps. In October 1941 Sabey was in an Austrian camp, where he saw the arrival of the first consignment of Russians when the temperature was almost at the freezing point. At the sight a long, low cry of rage swept up from the French prisoners' quarters, and next came angry cries from the British. The Russians were so emaciated that they seemed more like animals than human beings, and many who were unable to walk were supported by others. The British prisoners were so sickened that their attitude became ominous, and guards chased them into their huts. When the Russians were stripped for a shower bath their bones were almost sticking through their infested skins. The guards used whips and kicked and man-handled them.

The British, who had been refused permission to help the Russians, now pushed the guards aside and removed the seriously ill and the dead on stretchers. The corpses were so light from starvation that three could be placed on a single stretcher. A Russian told Sabey that the party traveled for six weeks through Germany without being able to leave the cattle trucks in which they were herded. Of 1,200 on the train, 300 died. An English medical officer, Capt. A. Webster, whom the Germans sent to attend the Russians, made the heroic decision of remaining with them voluntarily when his time was up. A team of Australians, New Zealanders and English medical orderlies voluntarily worked under him.

Penicillin Expert to Help Russia

Professor H. W. Florey, famous for his work on penicillin, has gone to Russia to pass on his knowledge to Soviet surgeons. He recently directed the use of penicillin for the treatment of wounds in the Middle East and has presented a report thereon to the Medical Research Council and the War Office.

BRAZIL

(From Our Regular Correspondent)

Feb. 6, 1944.

Vital Statistics of Rio de Janeiro for 1943

Provisional vital statistics for the city of Rio de Janeiro for the year 1943 are now available and may be compared with the figures for 1941 and 1942 (THE JOURNAL, May 2, 1942, p. 96; April 10, 1943, p. 1238). The population of the city as of July 1, 1943 was 1,890,000. The total number of deaths from all causes was 32,694, giving an annual death rate of 17.30 per thousand of population, which is just below the rate for the previous year (17.54). Practically, there has been no change in the death rate during the last twelve years, after a constant and regular decline since the beginning of the century. From 25 per thousand for the period 1902-1906 the mortality followed a descending trend to 17.88 for the period 1927-1931. The number of live births registered in 1943 was 41,728, representing an annual birth rate of 22.10 per thousand of population, a continued improvement over the previous two years (19.28 per thousand for 1941 and 21.16 per thousand for 1942). The infant mortality rate was 146 per thousand live births, an improvement over 1941 (180 per thousand live births) and 1942 (153 per thousand live births). This decline in the infant mortality rate is mainly due to the increase in the number of births registered, which may be accounted for, in part at least, by efforts to better birth registration. The fetal mortality was 74.17 per thousand total births, a figure showing practically no change in comparison with the last few years. This is accepted by Brazilian sanitarians principally as a result of the still high prevalence of syphilis in the population. The number of deaths from causes related to pregnancy, childbirth and the puerperium was 264, corresponding to a maternal death rate of 6.33 deaths per thousand live births (7.75 in 1942).

The most important cause of death was tuberculosis, with a total of 6,157 deaths (5,989 from tuberculosis of the respiratory system), or 18.83 per cent of the number of deaths from all causes. The tuberculosis death rate of 325 per hundred thousand of population may be compared with a rate of 345 per hundred thousand in the period 1922-1926, 327 in 1927-1931, 315 in 1932-1936 and 327 in 1937-1941. Tuberculosis is still the greatest health problem in Rio de Janeiro. The rest of the "infectious and parasitic diseases" caused 10,295 deaths (31.49 per cent of deaths from all causes), an annual death rate of 545 per hundred thousand, as against about 100 per hundred thousand for the average of the largest cities of the United States. Of this total, 109 deaths were caused by typhoid, an annual death rate of 5.77 per hundred thousand (7.17 in 1941, 6.26 in 1942 and 7.10 in the period 1937-1941). The other principal infections were dysentery (mainly bacillary), measles, whooping cough, diphtheria, malaria, influenza, leprosy, epidemic meningitis, epidemic encephalitis, poliomyelitis and tetanus (about 50 per cent umbilical). Cancer, which caused 1,362 deaths, or 72.06 per hundred thousand (66.44 in 1942, and 67.34 in 1937-1941), has increased steadily as a cause of death since 1903-1907, when the mean annual death rate was 34.75.

The second most important group of causes of death is diseases of the digestive system, represented by 5,371 deaths, or 16.43 per cent of the deaths from all causes, which corresponds to a rate of 284 per hundred thousand of population (275 in 1941 and 277 in 1942). A majority (3,468) of these deaths were listed as "diarrhea and enteritis under 2 years"—the greatest contribution to infant mortality. An average of 38 per cent of the deaths in the age group 0-1 year in Rio de Janeiro is classified as due to diarrheal diseases. The number of deaths caused by appendicitis was 95 and the number caused by diseases of the liver and the biliary ducts was 481, corresponding respectively to 5.03 and 25.45 per hundred thousand. The third leading group of causes of death was diseases of

the circulatory system, represented by a total of 5,116 deaths, or 271 per hundred thousand. Of this total, 4,084 deaths were caused by diseases of the heart, a rate of 216 per hundred thousand. The annual death rate from diseases of the cardiovascular system was increased in Rio de Janeiro from 173 per hundred thousand for the period 1926-1930 to 308 in 1941 and 308 in 1942. In 1943, however, the rate decreased, perhaps because of the important changes in the latest revision of the International List of Causes of Death, now in full use.

Diseases of the nervous system caused 1,236 deaths, or 65.40 per hundred thousand, the largest contribution being from "intracranial lesions of vascular origin" (877 deaths, or 46.40 per hundred thousand). The number of deaths registered as caused by diseases of the respiratory system was 4,039, a rate of 214 per hundred thousand. Diseases of the genitourinary system caused 1,689 deaths, or 89.37 per hundred thousand. Of this total, the deaths due to acute and chronic nephritis were 1,286, or 68.04 per hundred thousand. Puerperal septicemia and infection was the cause of 94 deaths, or 35.61 per cent of the maternal deaths (1 death in 444 live births as against 1 in 282 in 1941 and 1 in 321 in 1942). Violent deaths were 1,071, or 3.27 per cent of the total of deaths from all causes, which corresponds to a rate of 56.67 per hundred thousand (66.46 in 1941 and 65.51 in 1942). Of this total, 235 deaths were due to motor vehicle accidents, or 12.43 per hundred thousand (17.92 in 1941 and 10.68 in 1942).

Brief Items

Dr. João Marinho, professor of otorhinolaryngology at the University of Rio de Janeiro and distinguished practitioner of the specialty, has been elected a member of the Academy of Medicine of Buenos Aires, Argentina.

Dr. Alvaro Pontes, associate professor of surgery at the University of Rio de Janeiro, left for London recently at the invitation of the British Ministry of Health to study special problems of war surgery.

The University of Rio de Janeiro is now giving four special summer medical courses on the semeiology of the diseases of the nervous system, heredity in medicine, diseases of the extrapyramidal nervous system and syphilis of the nervous system. Drs. A. Borges Fortes, Helion Povoá, A. Moraes Austregesilo and Aloysio Marques respectively are in charge of these courses.

The Brazilian Temperance League promoted an "antialcohol week," during which several leading physicians and educators held special meeting and delivered lectures in schools, clinics, hospitals, factories and military posts. The opening address was delivered over the radio by Dr. Henrique Roxo, director of the Psychiatric Institute of the University of Rio de Janeiro and president of the Brazilian League of Mental Hygiene.

Marriages

PAUL STAHL MERTINS JR., Montgomery, Ala., to Miss Anne Moss of Birmingham at Del Rio, Texas, February 12.

JOHN W. CATHCART, Winnsboro, S. C., to Miss Margaret Virginia Caughman of Columbia, February 21.

EDWARD BUIST WELLS, Nashville, Tenn., to Miss Rosemary Lamprakes of Rochester, N. Y., February 19.

WILLIAM HUGH HALL to Miss Rosemary Patricia Dickinson, both of Charleston, S. C., February 22.

HARRY VINCENT HANLEY, Brooklyn, to Miss Marie Joan Gallagher of Goshen, N. Y., January 30.

BRUCE A. HARRIS JR., Brooklyn, to Miss Joan Leigh Maddy in Dallas, Texas, February 21.

JAMES J. BAYER, Perrysburg, Ohio, to Miss Evelyn Maxine Orians of Carey, February 19.

ARTHUR E. SCHULTZ, Detroit, to Miss Betty Ann Kralik of Cleveland, December 11.

JOHN WILLIAM ROSE to Miss Pauline Mims, both of Birmingham, Ala., recently.

Deaths

Frederic William Schlutz * noted pediatrician, died in the Albert Merritt Billings Hospital, Chicago, March 8, aged 63, of decompensation due to heart disease.

Dr. Schlutz was born in Greene, Iowa, Nov. 10, 1880. He studied at Wartburg College, Clinton, Iowa, and graduated at the University of Maryland School of Medicine, Baltimore, in 1902. Subsequently he studied in Berlin, Strassburg, Kiel, London, Paris and at Harvard. He joined the faculty of the University of Minnesota Medical School, Minneapolis, in 1910, serving until 1912 as instructor in biochemistry. He then started teaching pediatrics, serving as instructor, assistant professor and professor and head of the department. He also was professor of pediatrics at the Graduate School at Minnesota. It was during this period that he founded the Minneapolis Infant Welfare Society. In 1930 he was named to the faculty of the University of Chicago School of Medicine as professor and head of the department of pediatrics, serving also as chairman of the Bobs Roberts Memorial Hospital for Children. The following year he was named the first Richard T. Crane professor of pediatrics.

Certified by the American Board of Pediatrics, Dr. Schlutz was a member of the American Pediatric Society, American Academy of Pediatrics, Society for Pediatric Research, American Biochemical Society for Experimental Biology and Medicine, American Society of Biological Chemists, American Institute of Nutrition, Society for Research in Child Development, Institute of Medicine of Chicago and the Minnesota Academy of Medicine. He was an honorary member of the National Academy of Medicine of the Republic of Argentina and of the pediatric societies of Mexico, Uruguay, Paraguay, Argentina, Colombia, Peru and Cuba. He was United States delegate in a number of Pan American child hygiene congresses between 1928 and 1942 and this year was to serve similarly at the second pediatric congress in Mexico. He had been a member of the executive committee of the Pan American Union. At the time of his death he was preparing to leave for an eighteen weeks good will mission in Latin America for the U. S. Department of State. He was a committee member of the White House Conference on Child Health in 1929-1930.

Dr. Schlutz was assistant medical chief in charge of contagious diseases at the Base Hospital, 12th Division, Camp Evans, in 1918. He had written numerous articles dealing with his specialty, independently and in collaboration with others, and concluding his year as chairman of the Section on Diseases of Children of the American Medical Association, 1932-1933, he wrote a review of the section covering the first fifty years of its development.

Randle Crater Rosenberger * Rahns, Pa.; Jefferson Medical College of Philadelphia, 1894; in 1894 assistant in outpatient department diseases of children and assistant demonstrator of histology at his alma mater, where he was from 1895 to 1898 assistant demonstrator of normal and pathologic histology and assistant in diseases of the heart and lungs, in 1898-1899 demonstrator of normal histology and bacteriology, in 1900 demonstrator of bacteriology, in 1902 associate in bacteriology, from 1904 to 1908 assistant professor in bacteriology and from 1909 to 1924 professor of hygiene and bacteriology, serving concurrently during most of this period as curator of the museum; from 1924 to 1941 professor of preventive medicine and bacteriology and since the latter date professor of immunology and bacteriology; in 1941 served as acting dean of the college; lecturer on hygiene at the Woman's Medical College of Pennsylvania; member of the Society of American Bacteriologists, the College of Physicians of Philadelphia and the Philadelphia Pathological Society; in 1910 member of the Milk Commission of Philadelphia and in 1916 the Pneumonia Commission of Philadelphia; served as assistant pathologist and director of the clinical laboratory at the Philadelphia General Hospital, pathologist to St. Joseph's Hospital and associate in bacteriology and pathologist to the Henry Phipps Institute; died February 21, aged 70, of myeloblastic leukemia.

Albert Franklin Tyler * Omaha; John A. Creighton Medical College, Omaha, 1907; formerly professor of roentgenology and physical therapy at the Creighton University School of Medicine; president of the Omaha-Douglas County Medical Society in 1918, the Omaha Roentgen Society from 1918 to 1920 and the Radiological Society of North America in 1920; a founder of the American College of Physical Therapy, later known as the American Congress of Physical Therapy, of which he was president in 1933; received the gold key award of the society in 1932; member of the American Roentgen Ray Society, secretary of the central section from 1916 to 1918; member of the American Radium Society,

Omaha Mid-West Clinical Society, British Roentgen Society and the Nebraska Radiological Society; fellow of the American College of Physicians; specialist certified by the American Board of Radiology, Inc.; for many years on the staffs of the Immanuel Deaconess Institute and Creighton St. Joseph's Hospital; author of "Roentgenotherapy" and editor of "History of Medicine in Nebraska"; for many years publisher and managing editor of the *Journal of Radiology*, later known as the *Archives of Physical Therapy*; associate editor of the *Nebraska State Medical Journal* from 1917 to 1919; a trustee of the Nebraska Wesleyan University; died February 25, aged 62.

Adolph O. Pfingst * Louisville, Ky.; Louisville Medical College, 1891; M.D., University of Berlin, 1894; in 1895 became assistant to Prof. Herman Knapp and house surgeon to the New York Ophthalmic Institute; professor emeritus of ophthalmology at the University of Louisville School of Medicine, where he had been professor of physiology, histology and bacteriology and professor of ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society, International Society of Ophthalmology and the Pan American Congress of Ophthalmology; past president of the Kentucky State Ophthalmological Society and the Louisville Eye and Ear Society; fellow of the American College of Surgeons; director of the department of ophthalmology at the Louisville City Hospital from 1909 to 1930; member of the medical staffs of St. Joseph Infirmary, Norton Memorial Infirmary and Children's Free Hospital and the Kosair Crippled Children Hospital; member of the volunteer corps during World War I; author of "Textbook on Bacteriology" in 1898; served as associate editor of the *Kentucky State Medical Journal*; died February 25, aged 74, of coronary occlusion.

John van de Erve, Charleston, S. C.; Rush Medical College, Chicago, 1911; member of the South Carolina Medical Association and the South Carolina Academy of Science; professor emeritus of physiology at the Medical College of the State of South Carolina, where he had been professor of physiology since 1919 and for many years head of the department; chairman of the committee on buildings and grounds and member of the committee on curriculum at the college; formerly associate dean, professor and director of the department of physiology at the Marquette University School of Medicine, Milwaukee, and professor of physiology at the University of Alabama School of Medicine, Mobile; equipped and developed laboratories of physiology in Mobile, Milwaukee and Charleston; designed the building for physiology and pharmacology at Charleston; served as a lieutenant (jg) chaplain in the navy during World War I; also a Presbyterian minister; served as consul for the Netherlands; died February 15, aged 73, of coronary occlusion.

Sam Brock * Chicago; Johns Hopkins University School of Medicine, Baltimore, 1916; fellow of the American College of Surgeons; entered the Mayo Foundation, Rochester, Minn., as a fellow in surgery on July 1, 1919 and left the foundation in 1922; at one time associate in surgery, clinical assistant in surgery and instructor in surgery at the Northwestern University Medical School; formerly professor of surgery at the University of Georgia School of Medicine, Augusta; served as a major with the American Expeditionary Forces from 1917 to 1919, stationed at Base Hospital number 4; began active duty as a major in the medical corps, Army of the United States, in June 1942 and served for eighteen months in New Guinea during World War II; honorably discharged Sept. 29, 1943 because of ill health; on the staffs of the Passavant Memorial, Wesley Memorial and Edgewater hospitals; died in Rochester, Minn., February 11, aged 55.

Beveridge Harshaw Moore * Chicago; Rush Medical College, Chicago, 1912; associate professor of bone and joint surgery at the Northwestern University Medical School; specialist certified by the American Board of Orthopaedic Surgery, Inc.; member of the American Orthopaedic Association, the American Academy of Orthopaedic Surgeons, Chicago Orthopaedic Club, Institute of Medicine of Chicago, Chicago Literary Club and the American Association for the Advancement of Science; acting president of the Chicago Orthopaedic Society; a member of the committee on after-care and study of infantile paralysis, Visiting Nurse Association of Chicago; a major in the medical corps of the U. S. Army during World War I; chief surgeon, Shriners' Hospital for Crippled Children; served as attending orthopaedic surgeon at the Cook County and Children's Memorial hospitals; died February 29, aged 62, of coronary thrombosis.

William Byrdwill Peters, Appalachia, Va.; Hospital College of Medicine, Louisville, Ky., 1907; member of the Medical Society of Virginia; past president of the Wise County Medical Society; served during World War I; for many years medical director of the Appalachia Masonic Hospital; past president of the local chamber of commerce; director of the Portsmouth Navy Yard Clinic, Norfolk; for the past year served as chief surgeon of the Holston Ordnance Works at Kingsport, Tenn.; died in the Johns Hopkins Hospital, Baltimore, January 9, aged 61, of myocardial failure.

William Helweg Guillum ☉ Asbury Park, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1920; specialist certified by the American Board of Radiology, Inc.; member of the American College of Radiology; served as assistant roentgenologist, New York Post-Graduate Medical School and Hospital, Columbia University, and clinical assistant roentgenologist, New York Post-Graduate Medical School and Hospital, New York; on the staff of the Point Pleasant Hospital, Point Pleasant; died January 19, aged 59, of cerebral hemorrhage.

Leon Chappelle Agee, Whistler, Ala.; Harvard Medical School, Boston, 1943; an intern at the Jefferson Hospital, Roanoke, Va., where he died January 10, aged 22, of an enlarged thymus.

Francis Vernon Atkinson ☉ Washington, D. C.; George Washington University School of Medicine, Washington, 1915; died December 27, aged 69.

Mark N. Brooks, Springville, N. Y.; University of Buffalo School of Medicine, 1884; member of the Medical Society of the State of New York; died December 23, aged 82, of lobar pneumonia and general arteriosclerosis.

Guglielmo Cataldi, St. Louis; Regia Università degli Studi di Palermo Facoltà di Medicina e Chirurgia, Italy, 1897; died January 11, aged 72, of cerebral hemorrhage.

John Wyman Dean, Glens Falls, N. Y.; Albany (N. Y.) Medical College, 1897; member of the Medical Society of the State of New York; died December 18, aged 75, of endocarditis, influenza, myocarditis and arteriosclerosis.

David Derow, New York; Columbia University College of Physicians and Surgeons, New York, 1905; member of the Medical Society of the State of New York; on the staff of Beth Israel Hospital; died in the Mount Sinai Hospital December 25, aged 63, of bronchopneumonia.

Louis Phillip Dosh ☉ Elmsford, N. Y.; Cornell University Medical College, New York, 1903; head of the civilian defense medical services in Elmsford; for many years on the staff of the Tarrytown Hospital, Tarrytown, where he died, January 16, aged 63, of adenocarcinoma of the urinary bladder.

George S. Durbin ☉ Erie, Pa.; Jefferson Medical College of Philadelphia, 1918; on the staff of St. Vincent's Hospital; died December 25, aged 49, of cerebral hemorrhage.

Galen Lamar Eads, Marshall, Texas; Southern Methodist University Medical Department, Dallas, 1913; member of the State Medical Association of Texas; health officer of Harrison County and served as chairman of the county board of health; served during World War I; died December 26, aged 51, of injuries received in an automobile accident.

George Hurlburt Felton, Berea, Ky.; University of the City of New York Medical Department, New York, 1878; oldest alumnus of the Brown University, Providence, R. I.; at one time professor of natural science and mathematics and acting president at the Leland University in New Orleans and professor of materia medica in the Medical Department of New Orleans University; died in the Berea College Hospital December 7, aged 97, of chronic myocarditis.

Aline Fox, New York; Columbia University College of Physicians and Surgeons, New York, 1943; died December 6, aged 25, of an overdose of sedative.

Claud Frank Gilbert, Corinth, Miss.; University of Tennessee College of Medicine, Memphis, 1914; on the staff of Corinth Hospital; died January 19, aged 53, of carcinoma of the right arm and axilla.

James Treat Gorton, Yonkers, N. Y.; Cornell University Medical College, New York, 1900; member of the Medical Society of the State of New York; for many years medical director of the Otis Elevator Company; emeritus surgeon on the staff of St. John's Riverside Hospital, where he died January 23, aged 67, of carcinoma of the bladder.

Herman E. Hayd ☉ Buffalo; McGill University Faculty of Medicine, Montreal, Que., Canada, 1881; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; past vice president, president and treasurer of the American Association of Obstetricians, Gynecol-

ogists and Abdominal Surgeons; consulting surgeon, Deaconess and Memorial hospitals; formerly gynecologist at the Erie County Hospital; died February 18, aged 85, of myocarditis.

William W. Heberton, Avon, N. Y.; New York Homeopathic Medical College, New York, 1885; died December 29, aged 80, of coronary occlusion; angina pectoris and arteriosclerotic heart disease.

Edward Almond Hoffman, Turtle Creek, Pa.; Jefferson Medical College of Philadelphia, 1896; died in the Woodville State Hospital January 16, aged 70, of chronic myocarditis.

Isaiah Louis Hoffman, Brooklyn; Cornell University Medical College, New York, 1899; died December 31, aged 64, of coronary thrombosis, arteriosclerosis and hypertension.

Charles Henry Hunt, Portland, Maine; Medical School of Maine, Portland, 1905; member of the Maine Medical Association; fellow of the American College of Surgeons; chairman of the civilian defense medical unit; visiting surgeon, Maine General Hospital; district surgeon, Canadian National Railways; died suddenly January 27, aged 63, of coronary thrombosis.

Edward Worthington Jackson, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; veteran of the Spanish-American War; during World War I served with the secret service; served on the medical staff of the Commonwealth Edison Company; for many years on the staff of the Norwegian American Hospital; died in the Veterans Administration Facility, Hines, Ill., January 30, aged 67, of coronary arteriosclerotic heart disease with angina pectoris.

John Warren James, Dover, Del.; Jefferson Medical College of Philadelphia, 1895; president of the Medical Society of Delaware in 1922; served on the staff of the Kent General Hospital; died in Fort Lauderdale, Fla., December 13, aged 70, of coronary occlusion.

Alexander M. Kan ☉ Gary, Ind.; Illinois Medical College, Chicago, 1906; served during World War I; captain, medical reserve corps, U. S. Army, not on active duty; on the staff of St. Mary's Mercy Hospital, where he died January 31, aged 61, of carcinoma of the urinary bladder and prostate.

Charles Stephen Kennedy, Logan, Iowa; John A. Creighton Medical College, Omaha, 1902; member of the Iowa State Medical Society; also a pharmacist; past president of the Harrison County Medical Society; served during World War I; adviser to the Harrison County Insanity Commission and medical officer for the Selective Service; died January 13, aged 75, of heart disease.

Philip A. Kennicott, Hagerman, Idaho; College of Physicians and Surgeons of Chicago, 1889; died in Twin Falls January 11, aged 79, of carcinoma of the kidney.

John Joseph Kerrigan, Fall River, Mass.; College of Physicians and Surgeons, Baltimore, 1906; member of the New England Otolological and Laryngological Society; a member of the school board and formerly a member of the board of health; served on the staffs of the Massachusetts General Hospital and the Massachusetts Eye and Ear Infirmary, Boston, and St. Anne's, Union and Fall River General hospitals; died January 6, aged 65, of pulmonary embolism and chronic myocarditis.

James Washington King, Averill Park, N. Y.; Albany Medical College, 1884; at one time health officer of Stockport; died January 11, aged 87, of cerebral hemorrhage and general arteriosclerosis.

Louis Anatole LaGarde ☉ Lieutenant Colonel, U. S. Army, retired, San Francisco; George Washington University School of Medicine, Washington, D. C., 1912; Army Medical School, 1917; entered the medical corps of the U. S. Army as a first lieutenant on Dec. 18, 1917; promoted as a captain on Nov. 24, 1918, major April 6, 1929 and a lieutenant colonel on April 6, 1937; later retired; served during World War I; a physical examiner for the United Air Lines; died in Stockton December 2, aged 58.

Sidney Locock Lasell, Pasadena, Calif.; Columbia University College of Physicians and Surgeons, New York, 1899; for many years a medical missionary in China; died January 20, aged 73, of coronary occlusion.

Georgianna Strunk Loffredo, Jamestown, N. Y.; Eclectic Medical College of the City of New York, 1905; died December 27, aged 85, of general arteriosclerosis.

William Rodman Manning, Fillmore, Calif.; University of Southern California College of Medicine, Los Angeles, 1902; member of the California Medical Association; formerly health officer; served on the staff of the Foster Memorial Hospital, Ventura; died January 10, aged 68, of cerebral hemorrhage.

Edward George Marks, Kearny, N. J.; University of the City of New York Medical Department, 1894; member of the Medical Society of New Jersey; past president of the Academy of Medicine of Northern New Jersey; on the staff of the Presbyterian Hospital, Newark; died in the West Hudson Hospital January 16, aged 85, of arteriosclerotic heart disease.

Leon R. McCrummen, La Grange, Ga.; Atlanta College of Physicians and Surgeons, 1909; member of the Medical Association of Georgia; served as city physician; died January 15, aged 64, of heart disease.

Francis Humphrey Merrick * Boston; Boston University School of Medicine, 1933; assistant physician of the Boston College football team; served on the staffs of the Boston City and St. Elizabeth's hospitals; died in the Evans Memorial Hospital January 17, aged 37, of perforated ulcer and peritonitis.

Ephraim B. Miller, Fountaintown, Ind.; Medical College of Indiana, Indianapolis, 1897; died in the Methodist Hospital, Indianapolis, January 16, aged 78, of myelogenous leukemia.

Herbert Lee Montague, St. Louis; Washington University School of Medicine, St. Louis, 1896; a captain in the U. S. Army during World War I; died in the Veterans Administration Facility, Jefferson Barracks, Mo., January 9, aged 73, of cerebral thrombosis and generalized arteriosclerosis.

John Stephan Nagel * Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; past president of the Chicago Medical Society; councilor of the Third District of the Illinois State Medical Society; formerly professor of genitourinary surgery at the Illinois Postgraduate Medical School; dean and professor of genitourinary diseases at the Chicago College of Medicine and Surgery; specialist certified by the American Board of Urology, Inc.; attending surgeon, Garfield Park Community Hospital; died March 2, aged 70, of coronary thrombosis.

MAJOR JOSEPH B. COOPWOOD,
U. S. Army, 1907-1943

Daniel W. O'Brien * Brooklyn; Loyola

University School of Medicine, Chicago, 1925; served on the staffs of the Hospital of the Holy Family, St. Mary's Hospital, Bay Ridge Hospital, Victory Memorial Hospital and the Kings County Hospital, where he died January 24, aged 55, of acute coronary thrombosis and arteriosclerotic heart disease.

Simeon Anatol Oleynick * Elizabeth, N. J.; Albertus-Universität Medizinische Fakultät, Königsberg, Prussia, Germany, 1910; specialist certified by the American Board of Dermatology and Syphilology; served on the staffs of the Alexian Brothers Hospital, Elizabeth General Hospital and St. Elizabeth Hospital, Elizabeth, St. Michael's and Beth Israel hospitals in Newark; died January 17, aged 57, of carcinoma of the rectum with metastasis to the liver.

Clarendon Etheredge Oxner, West Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1928; member of the South Carolina Medical Association; died in the South Carolina Baptist Hospital, Columbia, January 7, aged 43, of acute nephritis.

Warren Ellis Page, Cranston, R. I.; Dartmouth Medical School, Hanover, N. H., 1881; served as health officer and medical inspector of schools; died January 8, aged 85, of pneumonia.

William Pfannebecker * Sigourney, Iowa; Missouri Medical College, St. Louis, 1891; member of the American Association of Railway Surgeons; examiner for many life insurance companies; died in the University Hospital, Iowa City, January 8, aged 80, of chronic prostatitis and uremia.

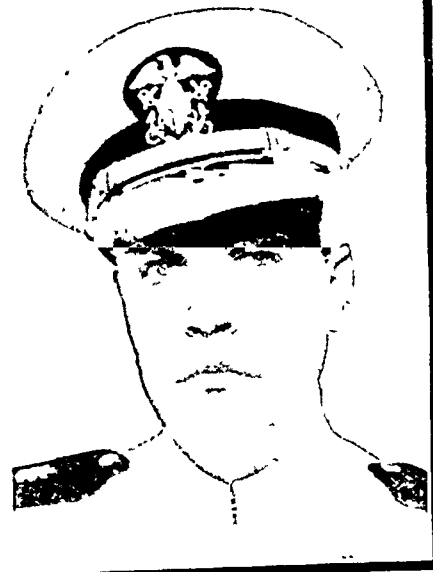

Eugene Adelbert Pond, Kansas City, Mo.; University Medical College of Kansas City, 1910; member of the Missouri State Medical Association; for many years physician for the Kansas City Stockyards Company and Commonwealth Aircraft, Inc.; formerly on the staff of Emergency Hospital, on the staffs of the St. Luke's Hospital, Trinity Lutheran Hospital and the Research Hospital, where he died January 10, aged 64, of pneumonia.

Louis Henri Renaud, Pawtucket, R. I.; School of Medicine and Surgery of Montreal, Que., Canada, 1904; died January 4, aged 63, of hypertensive cardiovascular renal disease, cardiac failure, uremia and hypertension.

Herbert Lowell Rich * Attleboro, Mass.; Tufts College Medical School, Boston, 1898; died in the Sturdy Memorial Hospital January 23, aged 78, of congestive heart disease.

Pettis Madison Richardson * Cushing, Okla.; Gate City Medical College, Texarkana, Ark., 1907; at one time associated with the Indian Service; city health officer; on the staff of the Masonic Hospital; died January 10, aged 65, of injuries received when the automobile in which he was driving was struck by a train.

Francis M. Roseberry, Keokuk, Iowa; College of Physicians and Surgeons, Keokuk, 1897; veteran of the Spanish-American War; died in the Graham Protestant Hospital January 6, aged 76, of cerebral hemorrhage.

LIEUT. EDWIN J. WELTE, U. S.
Naval Reserve, 1913-1943

Thomas Henry Shorb, Canton, Ohio; Ohio Medical University, Columbus, 1903; a captain in the medical corps of the U. S. Army during World War I; a member of the Canton Medical Library Association; at one time member of the city council and county coroner; served on the staff of the Aultman Hospital; died December 16, aged 68, of coronary occlusion.

Erra Delafield Stump, Charleston, W. Va.; Medical College of Ohio, Cincinnati, 1908; died March 1, aged 59, of cerebral hemorrhage.

Frank Lee Van Alstine * Jackson, Miss.; Hospital College of Medicine, Louisville, Ky., 1904;

on the staff of the Mississippi Baptist Hospital; at one time on the staff of the U. S. Marine Hospital, number 14, New Orleans; died January 2, aged 66.

Cecil Hendry Wilson * Bartow, Fla.; Atlanta College of Physicians and Surgeons, 1913; died December 18, aged 55, of carcinoma of the colon.

KILLED IN ACTION

Joseph Bennett Coopwood, Lockhart, Texas; Baylor University College of Medicine, Dallas, 1930; member of the State Medical Association of Texas; commissioned a captain in the U. S. Army (National Guard); extended active duty began Nov. 25, 1940 with the medical detachment, 141st Infantry, at Camp Bowie; later promoted to a major; killed in action in the North African area Nov. 21, 1943, aged 36.

Edwin Joseph Welte, Crookston, Minn.; University of Minnesota Medical School, Minneapolis, 1938; formerly fellow in surgery at the Minneapolis General Hospital; began active duty as a lieutenant (jg), medical corps, U. S. Naval Reserve, July 28, 1941 and later promoted to a lieutenant; killed in the battle of Tarawa in the Gilbert Islands when shell fire struck a landing boat, Nov. 20, 1943, aged 30.

Correspondence

FLUORIDE AND DENTAL CARIES

To the Editor:—Anent your stimulating editorial on fluoride and dental caries, together with the correspondence which it elicited in your issue of February 12, it seems that a geographic survey of disease in this country is much in order. For instance, are there other localities like Deaf Smith County, Texas, where dental caries is far below the average? And, conversely, in what districts do people have the poorest teeth? Even in Maryland, examination of army selectees has shown that those who come from the Eastern Shore have far better teeth than those who come from the western mountainous counties. And why stop with a consideration of teeth? There is a small region about 20 miles south of Rochester, N. Y., where the incidence of renal stones is high. A geologist called my attention to this condition and mentioned parenthetically that there was much gypsum in that area. The other side of this picture is represented by those localities that derive their drinking water from the Savannah River; gallstones and kidney stones are rare in those towns. Maine has been shown to have the highest incidence of cancer. Obviously there must be places in this country where the incidence of disease is less than in other places, and once such areas have been recognized the other problem, namely the economic problem of taking care of people who might gravitate to such regions in order to benefit from the natural advantages, may present itself for solution. But, first of all, why not have a geographic health survey to find out where any particular disease is common or rare? Such knowledge may be an important factor in helping to determine the cause and possible cure of that disease.

FERDINAND C. LEF, M.D., Baltimore.

STUDY OF INFANT DEATHS

To the Editor.—I have been interested in reading Dr. Edith L. Potter's article on "The Lessons to Be Learned from a Study of Infant Deaths" appearing in THE JOURNAL, February 5. The analysis of the causes of early infant deaths is illuminating, as is the account of the praiseworthy steps taken in Chicago to ameliorate these conditions.

In illustrating statistically the progress made in Chicago, however, I do raise the question of using the rates in the country as a whole as a background for comparison. Would it not be much more convincing to compare Chicago's position with other large cities—Detroit, New York, Cleveland, Philadelphia and others? When comparisons are made with the country as a whole, the cards are stacked against the smaller cities and the rural areas primarily because of lack of resources and facilities, the lesser opportunities for attracting professional skills and economic inability to take full advantage of the facilities that do exist.

Is it realistic to say that "what has been accomplished in this city can be accomplished anywhere if a sufficient number of people have a great enough desire." Is it just desire that is lacking, or is it in no small degree the wherewithal to satisfy that desire?

I am thinking of a rural county with low tax ratableity, 40,000 people and four doctors. How can they expect to provide good or adequate antepartum and obstetrical care? It isn't lack of desire. It is lack of ability to solve satisfactorily an array of tremendously difficult problems. Can the desire be realized until some power with greater ability than that of the county in question comes to improve the economic resources of the inhabitants?

Without in the slightest belittling the progress in Chicago, a comparison with the large cities would provide a better measuring stick. Chicago's infant mortality rate of 28.4 in 1942 is not greatly different from New York City's figure for that year, namely 28.8.

MARIE NYSWANDER, A.B.,
Cornell University Medical College,
New York 21.

ABBREVIATIONS IN PRESCRIPTION WRITING

To the Editor:—Will you give me the hospitality of space for a few words on the opinion expressed by your reviewer of L. C. Smith's "A Workbook of Elementary Pharmacology and Therapeutics" in your issue of Oct. 30, 1943?

I quite agree that abbreviations ought never to be used in prescriptions. They are a sign of laziness of spirit unworthy of a physician. I do not agree, however, when your reviewer says that Latin should not be used. Latin can be considered a universal language of pharmacology; its general use will do much for the necessary international application of medicine. Latin and the decimal system are the real expression of sound pharmacologic knowledge. As for the sentence "If they are Latin scholars it usually is at the expense of less knowledge of medicine and pharmacology" may I remind your reviewer of Mark Twain's lines "If your doctor know only medicine, you may be sure he does not know even medicine"?

Those physicians who know Greek and Latin and cultivate them, far from doing so at the expense of medical knowledge, improve, on the contrary, their medical skill by the clarity of logical thinking and the synthetic and intuitive approach to the patient which only a classical education gives.

A. P. CAWADIAS, M.D., F.R.C.P.,
50 Wimpole Street, London, W. 1.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, March 11, page 732.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: * Montgomery, Oct. 24-26. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

ARIZONA: * Phoenix, April 4-5. Sec., Dr. J. H. Patterson, 926 Security Bldg., Phoenix.

ARKANSAS: * March. Sec., Dr. D. L. Owens, Harrison. *Electric.* Little Rock, June 8. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: * San Francisco, June 27-29. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento.

COLORADO: * Denver, April 4-7. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT: * *Endorsement* New Haven, March 2. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DISTRICT OF COLUMBIA: * *Reciprocity.* Washington, March. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

FLORIDA: * Jacksonville, June 26-27. Sec., Dr. W. M. Rowlett, Box 786, Tampa.

ILLINOIS: * Chicago, April 4-6. Supt. of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.

INDIANA: * Indianapolis, May 2-4. Sec., Board of Medical Registration and Examination, Dr. W. C. Moore, 301 State House, Indianapolis.

KENTUCKY: * Louisville, Sept. 11-12. Sec., State Board of Health, Dr. Philip E. Blodgett, 620 S. Third St., Louisville.

MARYLAND: * Medical Baltimore, June 11-16. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 20-21. Sec., Dr. J. A. Evans, 612 W. 4th St., Baltimore.

MINNESOTA: * Minneapolis, April 18-20. Sec., Dr. J. E. D. P., 230 Lewis Medical Arts Bldg., St. Paul.

MISSOURI: St. Louis, August. Sec., State Board of Health, Dr. James Stewart, State Capitol Bldg., Jefferson City.

MONTANA: Helena, April 3-5. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

NEW MEXICO: Santa Fe, April 10-11. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NEW YORK: Albany, Buffalo, New York City and Syracuse, June 26-29. Sec., Dr. R. R. Hannon, Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, 415 S. Third St., Grand Forks.

OHIO: Endorsement, Columbus, April 4. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OREGON: Endorsement, Portland, April 22. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

RHODE ISLAND: Providence, April 6-7. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 26-28. Sec., Dr. N. B. Heyward, 1329 Mandeville St., Columbia.

TEXAS: Houston, March 22-24. Final date for filing application is March 10. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas.

WEST VIRGINIA: Charleston, May 1-3. Commissioner, Public Health Council, Dr. John F. Offner, State Capitol, Charleston.

WISCONSIN: Milwaukee, June 27-29. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

DISTRICT OF COLUMBIA: Washington, April 17-18. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 F. Municipal Bldg., Washington.

FLORIDA: Gainesville, June 8. Sec., Dr. J. P. Conn, John B. Stetson University, Deland.

IOWA: Des Moines, April 11. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor and Detroit, May 12-13. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: Minneapolis, April 1-5. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis.

NEBRASKA: Omaha, May 2-3. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.

SOUTH DAKOTA: Vermillion, June 4-5. Sec., Dr. G. M. Evans, Yankton.

WISCONSIN: Madison, April 1. Sec., Prof. R. N. Bauer, 152 W. Wisconsin Ave., Milwaukee.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Schools: Right to Expel Students Stealing and Selling Examination Questions: Necessity of Hearing Before Expulsion.—Questions of the examinations to be given in the College of Medicine of the University of Tennessee were stolen during the fore part of 1940 and were sold to students taking the examinations in question. The appropriate university authorities organized a student council, consisting of the Dean of the College of Medicine and twelve students, to investigate the situation and to make recommendations to the faculty. The council obtained evidence in the nature of statements from students connecting Sherman and Avakian, students in the College of Medicine, with the theft and sale of the questions, and the two students were called before the council. Both denied their guilt, but the council recommended their dismissal from the university. The two students were notified by the Dean of the College of Medicine to meet with the faculty executive committee on a certain day. Sherman refused to attend the meeting "because of business engagements." The committee expelled the two students from the university. Later Sherman asked for a rehearing, which was granted. At the rehearing there was read the substance of the testimony before the council against Sherman, and he was permitted to be heard in his own behalf. The same procedure was had with respect to Avakian. Apparently the committee did not recede from its previous position. Later the president of the university appointed a special committee from the board of trustees of the university to hear an appeal from the two students. At the meeting of this special committee the students were represented by coun-

sel. The substance of the testimony heard by the student council was read, and the students were permitted to testify and to introduce witnesses to rebut such testimony. However, they were not confronted then or at any other time face to face with their so-called accusers nor, obviously, were they given an opportunity to cross examine those persons. The special committee voted to affirm the action of the executive committee in expelling the students. Later separate mandamus actions were instituted on behalf of each student against the Dean of the College of Medicine, the president of the university, the members of the faculty executive committee and the special committee of the board of trustees to require the reinstatement in school of the students. From a decree in favor of the students, the defendants appealed to the Supreme Court of Tennessee.

In our opinion, said the Supreme Court, the hearings held prior to the final expulsion of the two students here involved were such as met the requirements of justice, both to the school and to the students, and the students were given a fair and reasonable opportunity to make their defense. While the governing authority in both public and private schools should have and does have the widest discretion in the matter of discipline, to the end that the honor and integrity of the school, as well as its scholastic standards, be maintained, that authority should recognize its responsibility to students whose honor and future destiny are within its keeping. We cannot agree with the contention of counsel for the students that a fair hearing prior to expulsion contemplates a trial as in a chancery court or in a court of law. We concur in the rule laid down in *Koblitz v. Western Reserve University*, 21 Ohio Cir. Ct. R. 144, as follows:

Custom, again, has established a rule. That rule is so uniform that it has become a rule of law; and, if the plaintiff had a contract with the university, he agreed to abide by that rule of law, and that rule of law is this: That in determining whether a student has been guilty of improper conduct that will tend to demoralize the school, it is not necessary that the professors should go through the formality of a trial. They should give the student whose conduct is being investigated every fair opportunity of showing his innocence. They should be careful in receiving evidence against him, they should weigh it, determine whether it comes from a source freighted with prejudice, determine the likelihood, by all surrounding circumstances, as to who is right, and then act upon it as jurors, with calmness, consideration and fair minds. When they have done this and reached a conclusion, they have done all that the law requires of them to do.

The governing authority, the court continued, of the College of Medicine has the inherent right to expel students for acts which are contrary to good morals, which tend to lower the standards of the school in any respect, and the authority is not required to follow technical rules or procedure in bringing to trial students who have committed an offense against the institution. An accused student should be informed as to the nature of the charges made against him and the names of at least the principal witnesses against him when requested, and he should be given a fair opportunity to make his defense. He cannot claim the privilege of cross examination as a matter of right. The testimony against him may be oral or written, not necessarily under oath, but he should be advised as to its nature as well as the persons who have accused him. Students should not be compelled to give evidence incriminating themselves or which might be regarded as detrimental to the best interests of the school. Every governing authority should impress on all students their duty to protect the honor and integrity of the school. As to a right to meet his accusers face to face in an investigation of wrongdoing, we cannot fail to note that honorable students do not like to be known as snoopers and informers against their fellows. A student informing against a fellow student should not be subjected to a cross examination, which could work to the informer's public humiliation. To subject the informer to cross examination would be subversive of the best interests of the school as well as harmful to the community.

Even though the right to study medicine and to practice medicine, continued the court, is a property right, it is a qualified right, qualified to the extent that one claiming the right cannot exercise it to the prejudice and injury of others and of organized society. The due process clause of the constitution has no application to an instance as here, where the governing board of a school has rightfully exercised its inherent authority to discipline students after due notice and a fair hearing and courts will not interfere with the discretion of school officials.

in matters affecting discipline of students unless there is a manifest abuse of discretion or where their action has been arbitrary or unlawful. Since such conditions are not present here, the court ordered the dismissal of the actions instituted by the students and in effect affirmed the order of the executive committee expelling them from the university. The Supreme Court of the United States subsequently denied certiorari.—*State ex rel. Sherman v. Hyman and State ex rel. Avakian v. Same*, 171 S. W. (2d) 822 (Tenn., 1942); 63 S. Ct. 1158.

Society Proceedings

COMING MEETINGS

- Alabama, Medical Association of the State of, Montgomery, April 18-20. Dr. D. L. Cannon, 519 Dexter Avenue, Montgomery, Secretary.
- American Association for Thoracic Surgery, Chicago, May 5-6. Dr. Richard H. Meade Jr., Kennedy General Hospital, Memphis, 15, Tenn., Secretary.
- American Association of Industrial Physicians and Surgeons, St. Louis, May 8-11. Dr. Edward C. Holmblad, 28 East Jackson Blvd., Chicago, Managing Director.
- American Association on Mental Deficiency, Philadelphia, May 11-15. Dr. Neil A. Dayton, Mansfield Training School, Mansfield Depot, Connecticut, Secretary.
- American Society for Clinical Investigation, Atlantic City, May 8. Dr. Wesley W. Spink, University Hospitals, Minneapolis, Secretary.
- Arizona State Medical Association, Phoenix, April 14-15. Dr. Frank J. Milloy, 112 N. Central Ave., Phoenix, Secretary.
- Arkansas Medical Society, Little Rock, April 17-18. Dr. W. R. Brooksher, 602 Garrison Avenue, Fort Smith, Secretary.
- Association of American Physicians, Atlantic City, May 9. Dr. Joseph T. Wearn, Lakeside Hospital, Cleveland, Secretary.
- Association of State and Territorial Health Officers, Washington, D. C., March 20-23. Dr. G. C. Ruhland, 300 Indiana Ave., N.W., Washington, D. C., Secretary.
- California Medical Association, Los Angeles, May 7-8. Dr. George H. Kress, 450 Sutter Street, San Francisco 8, Secretary.
- Conference of State and Provincial Health Authorities of North America, Washington, D. C., March 22. Dr. A. J. Chesley, State Office Building, St. Paul, Minn., Secretary.
- Connecticut State Medical Society, Bridgeport, May 2-4. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.
- Florida Medical Association, St. Petersburg, April 13-14. Dr. Shaler Richardson, 111 West Adams St., Jacksonville, Secretary.
- Georgia, Medical Association of, Savannah, May 9-12. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta, Secretary.
- Iowa State Medical Society, Des Moines, April 21-22. Dr. Robert L. Parker, 3510 Sixth Avenue, Des Moines, Secretary.
- Kansas Medical Society, Topeka, May 10-11. Dr. F. R. Croson, 112 West Sixth Street, Topeka, Secretary.
- Louisiana State Medical Society, New Orleans, April 24-26. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, 13, Secretary.
- Maryland, Medical and Chirurgical Faculty of, Baltimore, April 25-26. Dr. W. Houston Toulson, 1211 Cathedral St., Baltimore, Secretary.
- Minnesota State Medical Association, Rochester, April 13-15. Dr. B. B. Souster, 493 Lowry Medical Arts Bldg., St. Paul, Secretary.
- Mississippi State Medical Association, Jackson, May 9-10. Dr. T. M. Dye, Box 295, Clarksdale, Secretary.
- Missouri State Medical Association, Kansas City, April 23-25. Mr. Raymond McIntyre, 634 N. Grand Blvd., St. Louis, Executive Secretary.
- National Tuberculosis Association, Chicago, May 10-12. Dr. Charles J. Hatfield, 1790 Broadway, New York, Secretary.
- Nebraska State Medical Association, Omaha, May 1-4. Dr. R. B. Adams, 416 Federal Securities Bldg., Lincoln, Secretary.
- New Jersey, Medical Society of, Atlantic City, April 25-27. Dr. Alfred Stahl, 55 Lincoln Park, Newark, Secretary.
- New York, Medical Society of the State of, New York, May 8-11. Dr. Peter Irving, 292 Madison Ave., New York 17, Secretary.
- North Carolina, Medical Society of the State of, May 1-3. Dr. R. D. McMillan, P. O. Box 232, Red Springs, Secretary.
- Northern Tri-State Medical Association, Toledo, Ohio, April 11. Dr. Oscar P. Klotz, 127 W. Hardin St., Findlay, Ohio, Secretary.
- Ohio State Medical Association, Columbus, May 2-4. Mr. Charles S. Nelson, 79 E. State St., Columbus, Executive Secretary.
- Oklahoma State Medical Association, Tulsa, April 24-26. Dr. L. J. Moorman, 1200 N. Walker St., Oklahoma City, Secretary.
- Society of American Bacteriologists, New York, May 3-5. Dr. W. C. Frazier, 310 Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Tennessee State Medical Association, Nashville, April 11-13. Dr. H. H. Shoulders, 706 Church St., Nashville, Secretary.
- Texas, State Medical Association of, Dallas, May 10-11. Dr. Holman Taylor, 1404 W. El Paso Street, Fort Worth, Secretary.

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Sixteenth Annual Meeting, Held in Chicago, Nov. 5, 1943

The President, DR. JOHN WALKER MOORE,
Louisville, Ky., in the Chair

(Concluded from page 737)

Comparative Value of Blood Substitute Used for Experimental Shock

DR. C. C. SCOTT, H. M. WORTH, A.B., and E. B. ROBBINS, B.S., Indianapolis: Shock was produced in dogs by use of pneumatic venous tourniquets. In order to compare various blood substitutes effectively, animals were carried to the same level of shock. Unless given treatment, these animals all died. The volume of blood substitute injected was calculated as the amount necessary to decrease the hematocrit to the starting value. The fluid was given intravenously over a period of an hour immediately after removal of the tourniquets. Survival for two days was considered a cure. The blood substitutes tested were citrated dog plasma, heparinized dog plasma, 7 per cent gelatin, 3 per cent pectin, 3 per cent polyvinyl alcohol and 0.9 per cent saline solution. In each case 10 dogs were used, except that for citrated plasma and saline solution 20 animals were tested. The results were not significantly different for any of these blood substitutes. In another series of dogs carried to a deeper level of shock there was still no difference in the effectiveness of plasma and saline solution. In this type of shock, colloidal properties of the fluid used for treatment seemed to be of little importance in counteracting shock. It appeared that the effective part of the blood substitute was either water or saline solution.

DISCUSSION

DR. L. N. KATZ, Chicago: I believe that sodium chloride is the essence of treatment in the early stages of shock. When capillary permeability is altered so that the fluid can leak out, it is undoubtedly harmful. The practical value of these studies is that when one deals with soldiers at the front and when plasma is not quickly available, one can get good results by using saline solution in the early stages of shock. When the supply of plasma is limited, this procedure would save it for those cases in which trial by saline solution is not effective or for those cases in which shock is more advanced or in which hemorrhage has occurred.

DR. HEINRICH NECHELES, Chicago: Saline solution undoubtedly has its uses in early shock. I have produced more advanced traumatic shock in animals and treated them with saline solution, and all the animals died. I have repeated the experiments, and a high percentage of the animals treated with blood plasma or serum lived. I have taken as the index of the degree of shock the extent and the duration of the hypotension and the carbon dioxide content of the blood. I have found that with a carbon dioxide value and hypotension below certain levels none of the animals will survive regardless of the type of therapy. At higher levels the animals treated with colloidal substances, including plasma, will live. At these same advanced stages of shock saline solution leaves the circulation as fast as it is given. After a transient rise in the levels the blood pressure, carbon dioxide and plasma proteins drop more rapidly than before, and the downward course of the animals is accelerated. It is obvious that saline solution cannot replace plasma and colloid materials in the treatment of advanced shock. Each has its place, and one must be careful to specify the stage of shock under consideration.

DR. FRANK H. BETHELL, Ann Arbor, Mich.: I have produced traumatic shock in dogs, and the hemoconcentration precedes the drop in blood pressure. The burden cannot be carried by saline solution, but blood plasma will lead to recovery of the patient.

DR. CHARLEY J. SMYTH, Eloise, Mich.: During the past eighteen months Dr. S. D. Jacobson and I have determined the influence of the intravenous administration of a 5 per cent gelatin solution on the plasma volume in cases in which no detectable cardiovascular disease was present. A total of fifty-six injections of gelatin have been studied in 45 cases. The plasma volume is successfully elevated in all cases, and this elevation is maintained for an average of four hours. The average total

amount of gelatin recovered from the urine after forty-eight hours was 80 per cent of that injected. We have no evidence to indicate that gelatin is metabolized. In an effort to determine whether gelatin was effective in the treatment of cases of surgical shock we have used it in 30 cases and in all of them there has been a satisfactory clinical improvement in the blood pressure and in the rate and volume of the pulse. These observations indicate that this substance, which is readily available, can be given safely, is stable, is nonantigenic and warrants further clinical trial as a plasma substitute.

DR. NECHLES: Have you encountered plasma reactions in your dogs and have you had any difficulty from dog plasma? Dog plasma is often toxic, and consequently I was wondering if you had controls with injections of whole blood.

DR. SCOTT: In answer to Dr. Necheles, of 20 animals given citrated plasma, 10 received pooled plasma and the others were given unpooled plasma. Two dogs died during infusion, possibly from plasma reactions. However, they were excluded from the results. No reactions were observed in any other animals. Concerning the question of a possible relation between hemoconcentration and blood pressure fall, I reported to this meeting last year that we were unable to find any correlation in this respect. In dogs subjected to a shock procedure and given no treatment, there was no difference in degree of hemoconcentration in animals which died or recovered spontaneously. Hemoconcentration occurred mainly in the first two hours of the experiment. We do not claim that these results are a final answer to the problem of blood substitutes. Evaluation of treatment in shock is difficult. Our findings are based on experimental procedures different from those of other investigators; consequently, comparisons are difficult. It would be unfair for us to maintain that our results would hold true in other forms of shock.

DRS. R. H. LYONS, S. D. JACOBSON and JOHN NELKIN, Ann Arbor, Mich.: Comparisons have been made of the percentage change in hematocrit serum protein concentration, total circulating protein and red cell mass with the plasma volume by means of regression lines and the correlation coefficients.

Penicillin: Clinical Study of Its Therapeutic Effectiveness

DRS. PAUL O. HAGEMAN, SAMUEL P. MARTIN and W. BARRY OOD JR., St. Louis: As a part of cooperative investigation directed by the Committee on Chemotherapeutic and Other Agents of the National Research Council, 22 patients were treated with the sodium salt of penicillin. The drug was given intravenously every two to four hours in doses varying from 10,000 to 20,000 Oxford units. When intravenous injections were not practical, the intramuscular route was employed and individual doses were adjusted to the size of the patient and the severity of the infection. Intrathecal injections were used in the treatment of meningitis. Whenever localized and accessible foci of infection developed, penicillin was introduced directly into the site of infection. In a small group of patients with local infections the treatment was limited to the local use of the drug. The penicillin treatment was limited in most cases until signs of infection had subsided and the temperature had been normal for several days.

Nine patients with staphylococcal septicemia were treated, and all but 1 recovered. The 8 survivors included a child with purulent pericarditis, whose blood yielded 200 staphylococcus colonies per cubic centimeter, a young boy with 140 colonies per cubic centimeter of blood and acute osteomyelitis of the pelvis, and an infant with empyema and blood culture showing innumerable staphylococci. The 1 patient who failed to survive was suffering from an acute staphylococcal endocarditis and died following the rupture of a brain abscess.

Four patients with staphylococcal infections without bacteremia responded favorably to penicillin therapy. The infections in this group of cases were pneumonia and empyema, a post-operative wound infection, a chronic osteomyelitis of the humerus and a chronic osteomyelitis superimposed on a tuberculous hip infection. The last infection responded only temporarily to the chemotherapy.

Two patients with pneumococcal infections likewise responded favorably to penicillin treatment. The first patient entered the hospital with mastoiditis, lateral sinus thrombosis, petrositis,

meningitis and bacteremia due to the type III pneumococcus. In spite of the fulminating character of the infection she recovered completely following mastoidectomy, ligation of the jugular vein and penicillin treatment given intravenously, intrathecally and into the mastoid wound. The second patient was suffering from early empyema due to the type V pneumococcus. Penicillin was injected into the pleural cavity, and the infection subsided without surgical drainage.

Penicillin was also used with success in the treatment of a mixed postpneumectomy infection of the pleural cavity. One patient with agranulocytic angina recovered without complication following the use of penicillin.

Unfavorable results were encountered in the treatment of 3 patients with anaerobic streptococcal infection, all of whom ultimately died. Two patients with chronic pulmonary suppuration showed no response to the parenteral administration of penicillin.

Toxic reactions to penicillin were not observed. Although the therapeutic results were most gratifying in the treatment of even the most severe bacterial infections, it is suggested that they may be improved by the use of somewhat larger doses of penicillin than were used in the present study.

The Calcium Salt of Penicillin

DRS. WALLACE E. HERRELL and DONALD R. NICHOLS, Rochester, Minn.: We have studied a calcium salt of penicillin which was available in this country. Using the tissue culture method for the study of cytotoxicity of bactericidal agents previously described by Heilman and one of us (Herrell), it has been found that the calcium salt we used is less toxic for cellular elements than the now commonly used and completely safe sodium salt. The calcium salt in the dry state in sealed ampules kept away from the light at room temperatures for fifty-six days lost no potency. Further studies have also been made concerning the toxicity of the calcium salt. We have administered the calcium salt both intravenously and intramuscularly. The calcium salt has been found entirely satisfactory for the treatment of infections in human beings. Twelve cases of moderately severe and severe infections are included in the report. In all 12 the continuous intravenous drip technic was employed. The largest daily dose of the calcium salt of penicillin that was administered was 44,000 Oxford units. Since Florey and his associates considered therapeutic intravenous or intramuscular use of the calcium salt inadvisable, it seems possible that the calcium salt investigated by them differed in some way from the preparation studied by us.

DISCUSSION

DR. C. J. WATSON, Minneapolis: Dr. Wesley Spink is unable to be here, but here is a brief summary of his findings: The sodium salt of penicillin has been evaluated at the University of Minnesota Hospital in the treatment of 38 patients with various types of bacterial infections. Penicillin rapidly sterilizes the blood stream of patients having acute staphylococcal and hemolytic streptococcal bacteremia. While staphylococcal bacteremia may be controlled, associated bone lesions may appear to progress during and after therapy. Nevertheless the bones appear to recalcify without demonstrable residual infection. Penicillin was remarkably effective in the treatment of 5 cases of gonorrhea. Two of the 5 patients had a complicating tenosynovitis and arthritis, which was controlled with penicillin. Penicillin produced a remarkable therapeutic effect in an instance of pneumococcal bacteremia and empyema refractory to sulfonamide therapy and in 1 case of lung abscess of unknown cause. The latter case has not been followed long enough to determine the eventual outcome. Penicillin was without effect in the treatment of 3 patients with subacute bacterial endocarditis and 2 patients with pneumococcal meningitis. The local use of penicillin on 2 patients with staphylococcal skin lesions produced only temporary improvement. This mode of therapy merits further investigation. The treatment of 38 patients with penicillin was uncomplicated by toxic manifestations with the exception of 1 patient, who noted flushing of the face and who developed thrombophlebitis at the site where the material was injected.

DR. DOUGLAS DEEDS, Denver: I have treated 3 patients with the sodium salt of penicillin. My first case should not be counted as a penicillin failure, although it ended fatally. Fifty thousand Oxford units of penicillin was left over in solution in 1,000 cc. of isotonic solution of sodium chloride. I kept it in the ice box

for a little over five days and gave it by continuous intravenous drip over a twenty-four hour period to a patient in the forty-second day of his intractable sulfonamide resistant gonorrhea. The response was dramatic. Within twenty-four hours he was cured, left the hospital a few days later and has had no recurrence. The third patient was a boy with an acute osteomyelitis of the humerus complicated by staphylococcal septicemia. He was in poor condition, and sulfonamide therapy had not controlled his infection. Penicillin swung the tide in his favor, and he is now apparently well on the road to complete recovery. I am sure that he would have died without penicillin.

DR. E. L. DEGOWIN, Iowa City: A patient with septicemia due to hemolytic *Staphylococcus aureus* was moribund at the time she received penicillin. She had a large liver and was deeply jaundiced. There were 3,500 organisms per cubic centimeter in the blood stream. She was given 160,000 Oxford units of penicillin at one time. Four hours later there was less than 1 organism per cubic centimeter of blood. The patient then died of hepatic insufficiency. Only a few viable organisms could be cultured from the abscesses in the kidneys.

LIEUT. COMDR. D. H. ROSENBERG (MC), U.S.N.R., U. S. Naval Hospital, Great Lakes, Ill.: I should like to ask Dr. Hageman what dose of penicillin he used in the treatment of his patients with meningitis, and whether or not he noticed any reaction from the penicillin when used intrathecally. A patient with a septic form of scarlet fever complicated by acute otitis media had received prolonged sulfadiazine therapy without any beneficial effect. Fever had persisted, and on the eighteenth day of admission drowsiness, motor aphasia and right hemiparesis gradually appeared, followed later by recurrent colonic convulsions. The temperature rose to 105.4 F. A diagnosis of cerebral abscess (left temporofrontal) was made. He was given penicillin in doses of 40,000 Oxford units every two hours for two days. The dose was then reduced to 20,000 units every three hours and later to 10,000 units every three hours. His condition progressively improved, and the temperature returned to normal on the sixth day of therapy. A total of 2,360,000 Oxford units was used. This patient ultimately made a complete recovery. Comdr. L. L. Veseen has used penicillin in a number of cases of chronic gonorrheal urethritis and prostatitis which had been refractory to sulfonamide therapy. Within a few hours the urethral discharge diminished and the patients were fit for duty in two to four days. Similarly, in patients with sulfonamide resistant gonorrheal arthritis penicillin produced evident improvement in the joint symptoms within six to eight hours, and the temperature and pulse returned to normal within forty-eight hours.

DR. SPAFFORD ACKERLY, Louisville, Ky.: Have the authors had experience with chronic osteomyelitis?

DR. HAGEMAN: In answer to the question about intrathecal dosage, we injected 10,000 units intrathecally and observed no untoward reactions. Anaerobic streptococcal infections did not do well in our hands. It is our belief that these were undertreated. We did have 2 cases of chronic osteomyelitis, both of which cleared up under penicillin treatment. I should like to ask Dr. Herrell about dosage. It has struck me that the doses he employed have been smaller than we used. I wonder if he feels that we are overtreating our patients.

DR. HERRELL: As long as a solution of the sodium salt is kept in the ice box in a closed container, it does not lose potency as rapidly as is commonly believed. I have kept solutions of the sodium salt at ice box temperatures ($+5^{\circ}\text{C}$) for over a month with little, if any, loss of potency. The same is true of the calcium salt in solution. One should not therefore throw away solutions of penicillin that have been kept for a few days at ice box temperatures. Solutions of either of the salts kept at room temperature do lose potency rather rapidly. The sodium salt, even in the dry state, is not very stable at room temperatures, whereas the calcium salt appears to lose no potency at room temperature for a period of approximately two months. It is difficult to make final statements concerning the most desirable daily dose of penicillin for the treatment of infections. It is my feeling that the amounts I have used are satisfactory in most instances when the material is given by the intravenous drip method. Failures are sometimes accredited to inadequate

amounts of the material being used. On the other hand, the unsatisfactory results cannot all be explained on the basis of inadequate therapy. Regardless of how much penicillin is given, there are complications which develop in the treatment of sepsis which cannot be overcome by the chemotherapeutic agent regardless of how much is employed. There has been a feeling among some investigators that it is necessary to give penicillin to the point where it can be demonstrated in the blood stream by the methods now available for identifying it. When enough penicillin is present in the serum of patients being treated with penicillin to demonstrate its presence by these methods, the amount is far in excess of ordinary therapeutic requirements. This belief has received some confirmation in a recent communication from Fleming. A communication from Florey also is confirmatory. He found that when a patient has been given 100,000 units of penicillin in twenty-four hours by the intravenous drip method for acute sepsis the serum may be diluted a half with isotonic solution of sodium chloride and still there is present a complete inhibition of the test inoculum. This is merely a way of saying that 100,000 units a day is twice as much as is necessary with the intravenous drip treatment. For this reason I have rarely used more than 60,000 units a day. These opinions cannot be considered as final, but the whole question of dose should be carefully examined. If one can obtain satisfactory therapeutic results with 40,000 to 60,000 units in twenty-four hours instead of 100,000 to 200,000 units, it will mean that much penicillin saved for another patient.

Renal Damage Due to Sulfonamides

DRS. FRANCIS D. MURPHY, JOSEPH F. KUZMA, THEODORE Z. POLLEY and JOHN GRILL, Milwaukee: Kidney damage due to sulfonamides may result from the nephrotoxic action of the drug as well as from mechanical obstruction following crystal formation. Fourteen patients were studied, and the clinicopathologic results are reported here.

In 8 cases sulfathiazole was used, in 3 sulfadiazine, in 2 sulfanilamide and in 1 sulamyd. The doses of the drugs were given according to the accepted methods. In 5 of the 14 cases observed there was a mild albuminuria before the use of sulfonamides, and in 9 no evidence of kidney disorder. The first evidence of serious kidney disease after the use of sulfonamides was oliguria in 5 cases and anuria in 1 case. In the remaining 8 cases the first signs consisted of heavy albuminuria, many red blood cells, pus cells and casts. Other evidences of renal impairment were generalized edema in 1 case and some nitrogen retention in all cases. In 5 cases the onset was on the fifth day after the beginning of treatment. In 2 instances it occurred on the first day, and in another 2 on the third day. In the other cases the earliest signs of kidney damage occurred on the second, fourth, seventh, eighth and ninth days respectively. Blood levels at the time of recognition of kidney injury varied from 3.9 to 16.7 mg. per hundred cubic centimeters. Uremia due to sulfonamide intoxication caused death in 6 cases. Streptococcal septicemia was responsible for one death: (1) lobar pneumonia with lung abscess, (2) sepsis and generalized peritonitis after cesarean section, (3) cirrhosis of the liver and bronchial pneumonia, (4) glomerulonephritis superimposed on diabetes and (5) bronchopneumonia with massive lung collapse. In the other case, decapsulation of the kidney was successfully done and a section removed for biopsy.

The pathologic changes in the kidney attending sulfonamide therapy may be divided into two main groups; the first results from mechanical damage to the kidney, and the second from the toxic action of sulfonamides on the renal parenchyma.

DISCUSSION

DR. FRANCIS D. MURPHY, Milwaukee: When so-called nephrotoxic lesions occur in the kidney there is difficulty in healing them. Formerly it was believed that diminishing output of urine was fair warning that the kidney was badly damaged, and the corollary was that with diminishing oliguria the kidney damage had begun to heal. We are not sure that this holds good in the sulfonamide nephrotoxic kidney. Albuminuria is not a strict contraindication to the use of these drugs. There are cases of acute nephritis in which albuminuria disappeared under the use of sulfonamides.

DR. C. J. WATSON, Minneapolis: With sulfanilamide and sulfapyridine it was relatively unimportant whether the urine was alkaline or acid. It is entirely different with sulfadiazine and sulfamerazine. Dr. Wendell Hall and Dr. Wesley Spink at the University of Minnesota Hospital have been able to maintain blood levels of 40 to 60 mg. per hundred cubic centimeters of these compounds for a number of days without any evidence of renal damage if the pH of the urine is kept above 7.0 continuously. This is achieved by giving sodium bicarbonate frequently and in adequate amount.

DR. SPATFORD ACKERLY, Louisville, Ky.: I should like to ask how frequently drug rash and drug fever preceded these reactions.

DR. ARMAND J. QUICK, Milwaukee: Is it not possible to look on this untoward action of the drug as being similar to that produced in the liver by cinchophen after sensitivity to that drug has been produced? In other words, can we consider the kidney as having become sensitized?

DR. K. K. CHEN, Indianapolis: In experimental animals sulfanilamide does not produce renal lesions. We have incorporated this drug in the food to the extent of 5 per cent. Some animals will die, but we cannot find any kidney lesions. Sulfapyridine or sulfadiazine given in the same manner uniformly produces renal damage. In clinical literature I have gained the impression that it is rare to have kidney lesions with sulfanilamide. I should like to be informed how often the authors have encountered renal damage as a result of sulfanilamide therapy.

DR. KUZMA: Precipitation of the sulfonamides is one thing and nephrotoxic action on the kidney is another. They may be present at the same time, or one may follow the other. Many cases of crystalluria followed a nephrotoxic condition. If alkalinity of the urine is maintained, it will prevent crystallization of the sulfonamides. On the other hand, it does not prevent the nephrotoxic complications. The changes we observed were minimal. However, simple tubular degeneration and glomerular swelling do occur even with sulfanilamide.

Gold Toxicity in Relation to Gold Salt Therapy for Rheumatoid Arthritis

DR. R. H. FREYBERG, W. D. BLOCK, PH.D., and W. S. PRISON, PH.D., Ann Arbor, Mich.: To learn more concerning tissue damage which might result from gold, rats were injected with equivalent amounts of gold contained in compounds with grossly different chemical and physical properties. Results showed that soluble gold salts (gold eliminated chiefly in urine) when given in large amounts (much larger than compared with therapeutic doses) invariably cause severe damage to renal tubules which contain large amounts of precipitate of the heavy metal, moderate glomerular damage and albuminuria. The severity of pathologic changes was in direct proportion to the amount of gold injected. No other organs showed any important pathologic change. Oil suspensions of crystalline gold salts produced renal lesions in proportion to the solubility of the salt or the availability of the gold. Colloidal gold preparations (gold largely retained) caused no important renal disorder but produced livers and spleens packed full of the heavy metal phagocytized in the reticuloendothelial cells. The parenchymatous cells of the respective organs were damaged in proportion to the amount of phagocytosis. With all the preparations studied the histologic changes were proportional to the amount of gold found (by chemical analysis) in organs of rats injected with gold preparation in identical manner.

These animal studies indicate that gold may act as a parenchymatous poison and show the nature of the pathologic change. The possibility that in some patients a difference in absorption or excretion rate might account for toxicity was considered. When it became possible to determine accurately plasma concentration and urinary content of gold we hoped that chemical measurements might control treatment to allow adequate dosage for satisfactory therapeutic effect and prevent overdosage toxicity, comparable to chemical control of thiocyanate therapy for hypertension. This has not been possible. Toxicity has developed in some patients having plasma gold concentration and urinary excretion of gold less than, comparable to or in excess of average values for patients similarly treated, without toxicity. Skin biopsies from portions of the integument showing gold dermatitis contained gold in amounts comparable to normal skin

of nontoxic patients similarly treated. Gold toxicity developed in arthritic patients with normal as well as deficient blood ascorbic acid.

It appears therefore that gold toxicity in human beings is seldom due to parenchymatous poisoning effects except in some cases of nephritis. There are many indications that clinical toxicity is most often an allergic type of reaction. Patch tests using soluble salts commonly employed in treatment failed to indicate skin sensitivity in the patients who had dermatitis or other types of toxic reactions. Elemental gold and the chemical combinations of gold used in treatment seem not to be responsible for an allergic toxic reaction. Because gold injected in any form is found to circulate in intimate combination with serum protein almost entirely it was suggested that a gold proteinate may be allergenic in "toxic individuals." Intradermal injections with mixtures of gold salts and human serum or plasma (containing gold in an amount comparable to that usually found during treatment and some mixtures with tenfold gold concentration) produced no more positive skin reactions in patients with clinical gold toxicity than in gold treated patients without toxicity or other control subjects.

The nature of the suspected allergen responsible for most instances of gold toxicity remains obscure. The major factor of clinical importance in regard to toxicity from gold used in the treatment of arthritis is the speed of administration of the drug.

Treatment of Multiple Sclerosis by the Intravenous Administration of Histamine

DRS. BAYARD T. HORTON, H. P. WAGENER, J. A. AITA and H. W. WOLTMAN, Rochester, Minn.: Of 24 among 102 patients the disease may be regarded as acute; that is, the patients had had symptoms of multiple sclerosis for a period of a few weeks to a month or two, whereas the remaining 78 patients had had symptoms from one to twenty years. Many of the patients who had an acute form of the disease were more incapacitated than those who had a chronic form, as evidenced by the fact that many were brought to the clinic on stretchers and in wheelchairs. Their ages ranged from 16 to 58 years. Fifty-two were males and 50 were females.

Treatment consisted in the daily intravenous administration of 2.75 mg. of histamine diphosphate in 250 cc. of isotonic solution of sodium chloride at the rate of 30 to 90 minims (2 to 6 cc.) per minute, depending on the tolerance of the patient. The average patient received forty to fifty such injections; the minimal number was thirteen and the maximal number was three hundred. The prompt improvement that follows histamine therapy probably results from vasodilatation in the central nervous system.

Of the 24 patients who had an acute form of the disease, 18 are essentially clinically well, 1 has shown 70 per cent improvement, 1 50 per cent improvement and 1 40 per cent improvement, and 3 have shown no improvement. Two of the latter 3 are still receiving treatment.

Of the 78 who had an advanced or chronic form of the disease, 36 have shown varying degrees of improvement, ranging from 10 to 95 per cent. The remaining 42 patients have shown no objective improvement, although many were subjectively improved.

In subjects with ocular manifestations, such as the loss of vision and paralysis of the ocular muscles, the recovery seems to have been more rapid and complete with histamine therapy than we have observed in other forms of therapy.

We have given a total of six thousand injections without any ill effects except that 1 man, aged 20, had an acute gastric ulcer develop after thirteen injections had been administered. It healed completely within twelve days. Symptoms of multiple sclerosis disappeared. The patient previously had received twenty-four intravenous injections of typhoid vaccine in three months without any apparent improvement.

No type of therapy will be wholly effective in cases of advanced multiple sclerosis in which gliosis has occurred. Spontaneous remissions occur in many instances, so that it is difficult at present to evaluate fully this type of therapy. Early diagnosis is important and, if treatment is carried out before irreversible changes occur in the central nervous system, one may accomplish a great deal.

DISCUSSION

DR. H. P. WAGENER, Rochester, Minn.: Here is an interesting experimental therapy that permits the patient to be ambulatory as opposed to the confining routine of typhoid vaccine treatment, for example. It is carried out without danger and easily administered. We have been impressed by the prompt relief from neurologic signs and symptoms in certain cases at Dr. Horton's laboratory. Yet we know that the disappearance of signs and symptoms is one of the spontaneous and most characteristic features of multiple sclerosis itself. Practically every report of a new treatment for multiple sclerosis is colored with favorable, if not even enthusiastic, presentation of data. These cases have been followed only fifteen months at the most. It will take at least five years to evaluate fully the effect of this treatment on a large number of patients, preferably over a hundred in number.

DR. J. A. AITA, Rochester, Minn.: In a person suffering from multiple sclerosis, retrobulbar optic neuritis may develop in an acute or in a chronic progressive form. In the acute form, with abrupt onset and rapid loss of vision even to the point of complete blindness, a tendency to spontaneous recovery is present in the majority of cases. Employment of some type of vasodilator therapy appears to shorten the period of disability and distinctly improves the visual end results, especially in cases of severe or total primary loss of vision. Histamine given intravenously has proved to be an adequate and highly satisfactory substitute for the methods of treatment employed formerly, notably typhoid vaccine or other forms of foreign protein. It is more universally applicable, is less discommoding to the patient, does not necessitate hospitalization and, on the average, results in a more rapid and complete recovery of vision. The prognosis for recovery or maintenance of vision in the chronic progressive form of retrobulbar neuritis has always been poor in spite of the employment of any of the suggested forms of treatment. Administration of histamine intravenously has resulted in moderate improvement of vision in some cases. In the main, however, this improvement has proved to be only temporary. The nystagmus and paralyzes of conjugate ocular rotations and of individual eye muscles occurring in patients with multiple sclerosis cause considerable disability, especially when they are of rapid or sudden onset. I have noted the rapid return to essentially normal of the strength and balance of the ocular muscles which occurs in most instances under histamine therapy and the consequent improvement in the coordination of the patient in walking and in occupations or pursuits requiring use of the eyes.

DR. THEODORE L. SQUIER, Milwaukee: This presentation has been of special interest because of the similarity of histamine and allergic reactions and because of clinical improvement observed in 2 patients seen in 1938 and 1939, in each of whom a diagnosis of multiple sclerosis had been made. In the first patient studied for an allergic etiology of thrombocytopenic purpura a diagnosis of multiple sclerosis had been made eight years previously, and symptoms were present at the time of study. The second patient seen because of migraine present since childhood had had relatively recent manifestations of multiple sclerosis in which diagnosis neurologic consultants had concurred. Clinical food sensitivities were demonstrated in both patients, and in both not only were the presenting symptoms of purpura and migraine respectively relieved by specific food avoidance but, in addition, striking improvement occurred in the symptoms of multiple sclerosis. Because of dramatic and long continued improvement, it was felt justified in December 1942 to make an allergic study of another patient who had an acute, rapidly progressive multiple sclerosis of five months' duration and in whom there was a background of eczema, asthma and recent recurrent urticaria. When seen, she was unable to walk, had considerable visual disturbance and considerable impairment of speech. Following specific food eliminations she made a complete subjective and objective recovery within a period of about three months, so that she was able to return to all her normal activities. Recent work, especially that of Putnam and his associates, has suggested that vascular abnormalities may be fundamentally responsible for the pathologic changes occurring in multiple sclerosis; and these changes are essentially identical with those described by Abel and Schenck in the living blood vessels of rabbits during anaphylactic shock. There is a plausi-

ble basis for an allergic etiology, which if proved true even for only part of the cases, is an important contribution to management. Competent allergic investigation should precede histamine therapy. Recently I have seen 2 patients each of whom had been given intravenous histamine therapy elsewhere, who had relapses during the course of such therapy. My belief is that histamine therapy for most allergic conditions is disappointing.

DR. HORTON: We think of multiple sclerosis as a primary vascular disorder of the central nervous system with secondary changes in the nervous and interstitial tissues. As to what role allergy plays, we do not know. However, we have noted the association of hives and the onset of symptoms of acute multiple sclerosis in 1 instance. The whole problem resolves itself around the treatment of the acute phase. Early diagnosis is important, and treatment should be instituted before irreversible changes occur in the central nervous system. In cases in which the disease is advanced and the nerve elements have been replaced by neuroglia, no type of therapy will help. It may require years to evaluate histamine therapy in multiple sclerosis, but it is interesting to note that the first 3 patients so treated have remained clinically well for more than a year.

Effect on Carbohydrate Metabolism of Pork Adrenal Cortex Extract

DRS. CYRIL M. MACBRYDE and F. A. DE LA BALZE, St. Louis: In 5 of 26 of our patients with Addison's disease, hypoglycemia has been severe enough to cause frequent symptoms, and muscular weakness has been prominent. These symptoms have continued to occur in spite of adequate control of the electrolyte and water metabolism and of the blood pressure with desoxycorticosterone or beef adrenal cortex extract.

DISCUSSION

DR. DWIGHT J. INGLE, Kalamazoo, Mich.: The concentrate of hog adrenal extract is on clinical trial to test its usefulness in controlling carbohydrate metabolism and in maintaining resistance of patients who cannot be satisfactorily maintained on other forms of therapy. It is gratifying to hear of the encouraging results obtained by Dr. MacBryde and his associates.

DR. SAMUEL SOSKIN, Chicago: I agree with Drs. MacBryde and de la Balze as to the metabolic effects of adrenal cortex extracts; particularly as regards the statement that their action is exerted primarily by stimulating gluconeogenesis in the liver and not by depressing the assimilation of dextrose by the muscles. In this the cortical extracts resemble those of the anterior pituitary.

DR. MACBRYDE: When large amounts of adrenal cortex extract are given experimentally there is no doubt that excessively rapid gluconeogenesis can be produced and that a state resembling diabetes results. Under such conditions the utilization of carbohydrate is certainly hampered and not facilitated.

Plasma Protein Studies in Addison's Disease: Tiselius Electrophoresis Method

DR. E. PERRY McCULLAGH and LENA A. LEWIS, PH.D., Cleveland: Studies were made in the electrophoresis apparatus using phosphate buffer solution pH 7.8 according to the method of Longworth. When the patient had symptoms of definite adrenal insufficiency there was an increased total plasma protein. The albumin, both in terms of percentage and in actual grams per hundred cubic centimeters, was decreased and the total globulin increased. The greatest increase was observed in the beta and gamma globulin, although all the globulin fractions were in the normal range or above. When the patient was well maintained, whether on desoxycorticosterone acetate pellets or desoxycorticosterone acetate pellets and adrenal extract (about 7 cc. of commercial adrenal extract per day) the plasma protein picture failed to become entirely normal. The total protein was in the normal range, but the albumin remained low.

It appeared that, with the dosages of adrenal extract and desoxycorticosterone acetate employed, some essential factor for the maintenance of a normal plasma protein picture was lacking or at least inadequate.

DISCUSSION

DR. C. J. WATSON, Minneapolis: Has the cholesterol flocculation test been tried?

DR. E. PERRY McCULLAGH, Cleveland: The cholesterol flocculation test has not been tried.

DR. WATSON: Is the test the same whether it is due to removal or to tuberculosis?

DR. McCULLAGH: Yes, the same. In 1 case which showed active tuberculosis the α globulin was higher than in the other cases.

Alloxan Diabetes in Dogs

DRS. MARTIN G. GOLDNER and GEORGE GOMORI, Chicago: A single intravenous injection of 50 mg. per kilogram of alloxan given to dogs causes sustained diabetes mellitus. A larger dose (100 mg. per kilogram or more) in a single injection may be fatal within a few hours or may cause a hyperglycemic-uremic syndrome (75 to 100 mg. per kilogram), to which the dogs succumb within four to seven days. A smaller dose (25 mg. per kilogram) does not produce clinical symptoms in dogs.

Alloxan diabetes in dogs is characterized clinically by polydipsia, polyuria and weight loss, by hyperglycemia and glycosuria and by hyperlipemia, which usually develops during the second or third week. The dextrose tolerance test shows a typical diabetic curve. Alloxan diabetes in dogs is insulin sensitive and can be treated with insulin. Insulin, however, does not prevent the development of diabetes if given together with alloxan. Histologically, the beta cells of the islets of Langerhans are degranulated and may disappear completely, the alpha cells appear normal, the small pancreatic ducts show vacuolization, the kidneys show glycogen deposition, and fatty degeneration of the liver is found in later stages. Bioassay for insulin in the pancreases of 2 alloxan diabetic dogs showed very low values. There seems to be no tendency to spontaneous recovery. Some dogs have survived for more than two months and have remained diabetic.

Alloxan has been proved to act on the pancreatic islet cells. It may, however, also have a primary effect on the liver. In larger doses it affects also the kidney parenchyma.

Stimulatory Effect of Diabetogenic Anterior Pituitary Extract on Pancreatic Islet Function in Human Organic Hyperinsulinism

DR. JEROME W. CONN and LAWRENCE LOUIS, Sc.D., Ann Arbor, Mich.: Two patients suffering from spontaneous hypoglycemia due to organic hyperinsulinism (pancreatic insuloma) were studied. After a control period on constant diet high in carbohydrate, 5 to 10 cc. of a clear extract of beef anterior pituitary gland (sterilized at 0 C. by Berkefeld filtration) was given daily subcutaneously. Daily fasting blood sugar levels, nitrogen balance and serial dextrose tolerance tests were obtained.

During three courses of injections (eight, thirteen and twenty-three days) in the 2 patients an evident fall of the fasting blood sugar level occurred. On cessation of injections the level rose to or above the control level. During the injection periods the average level of the fasting blood sugar was depressed 48, 38 and 36 per cent respectively below the control levels. The absolute fall of the average blood sugar was 20 mg. per hundred cubic centimeters in all 3 cases (42 to 22, 50 to 31 and 59 to 39).

In the 1 case in which three successive courses of injections were given the third course failed to depress the fasting level of blood sugar, which at that time began to rise slowly above the control level. This patient was operated on after his third course of injections. An encapsulated insuloma was removed, with complete relief of the hypoglycemic state. Biopsy of normal pancreas was also obtained. Microscopically the tumor had some characteristics of carcinoma. Special islet cell staining techniques are being applied to the normal and abnormal pancreatic tissue. The second patient refused operation.

It appears that, with the amounts of diabetogenic material used, an initial stimulatory effect on pancreatic islet tissue function was obtained in 2 cases of organic hyperinsulinism. Hyperglycemia played no role in the stimulatory effect, since it was consistently absent.

DISCUSSION

DR. HENRY T. RICKETTS, Chicago: Why did not Drs. Conn and Louis continue the injections for a longer time and support the patient with dextrose with the idea of producing exhaustion of the islets, which they say can be done with this extract in dogs?

DR. CONN: It is conceivable that continuation with this type of treatment for a much longer time and with larger doses could lead to eventual "overwork degeneration" of the large amount of functioning islet tissue. If the stimulus was sufficiently great to overcome the ability of the islet tissue to respond, degeneration would result. The effect of so-called diabetogenic anterior pituitary extract appears to be directly on and stimulatory to the islets of Langerhans.

Effect of Phosphorus Feeding on the Phosphorus Metabolism in Hyperthyroidism

DR. I. DARIN PUPPEL, DR. HAROLD T. GROSS, ESTHER HIERDLE, M.S., and DR. GEORGE M. CURTIS, Columbus, Ohio: We have investigated 4 normal persons over a total period of forty-eight days of low phosphorus feeding. They all remained in slight negative phosphorus balance. Five hyperthyroid patients similarly studied over a period of thirty-three days showed an increase in the loss of phosphorus over the intake. This was eight or nine times the normal loss, owing to an increase in the excretion of phosphorus both through the gastrointestinal and through the urinary system. The blood phosphorus in many serial studies almost always remained within normal limits. The disturbances in the phosphorus metabolism were similar to those of the calcium metabolism and thus different from those of hyperparathyroidism. In diffuse toxic goiter the average loss of phosphorus was twice as great as in toxic nodular goiter. This difference remained true even in comparing the phosphorus balance of a toxic nodular goiter patient with that of one with diffuse toxic goiter whose basal metabolic rate was at almost the same level.

For several years we have given a high calcium, phosphorus and vitamin D diet preoperatively to patients with hyperthyroidism. Not one has subsequently developed so-called thyroid crisis. No deleterious effects have been noted. Certain patients with impending thyroid crisis subsequent to the prolonged administration of iodine were treated successfully and more quickly prepared for surgery by use of extra amounts of calcium, phosphorus and vitamin D without employment of an iodine vacation.

Because of the clinical significance of these observations, we determined the effects on the phosphorus metabolism of feeding various compounds and combinations of calcium, phosphorus and vitamin D, including a high phosphorus diet, calcium gluconate, calcium lactate plus drisdol and dicalcium phosphate with viosterol by mouth, as well as calcium chloride by vein. In 5 patients with hyperthyroidism studied over a period of sixty-six days these extra amounts of phosphorus abruptly stopped the negative phosphorus balance. In most instances an immediate great retention occurred with development of a manifest positive balance. We have supplemented the high phosphorus diet with four of the most common types of calcium salts in therapy. They were all effective in maintaining retention of phosphorus. However, in this series wafers of dicalcium phosphate with viosterol were instrumental in producing the most conspicuous retention.

DISCUSSION

DR. E. L. SEVRINGHAUS, Madison, Wis.: Phosphorus and nitrogen will be deposited in these cases. To set up the procedure to get a high phosphorus diet there will usually be a high nitrogen diet. I wonder if Dr. Puppel has any data to show there is a high phosphorus retention without a high nitrogen. If so, the criticism that it is due to improved protein retention would not be necessary.

DR. PUPPEL: We took into consideration the nitrogen balance because it has been shown that this usually remains negative in the hyperthyroid patient unless excess protein is given to maintain a positive balance. We did not do nitrogen balance studies. It has been shown previously that the nitrogen balance usually remains positive if the patient is maintained with a daily intake of at least 1 Gm. of protein per kilogram of body weight and if the patient does not lose weight. We applied the latter clinical facts; that is, these patients were maintained at a constant weight throughout the low and high phosphorus feeding; the protein content of both the high and the low phosphorus diets was kept constant at 1.5 to 2 Gm. daily per kilogram of body weight. The caloric intake was kept at a high level of basal plus 10 to 20 per cent. The fat intake was kept low.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Electrocardiographic Observations in Young Adults.—Viscidi and Geiger made electrocardiographic studies on 500 apparently healthy working adults between the ages of 18 and 38 years. There was an equal number of males and females. The studies disclosed that half of the records fell outside the range of normal on the basis of authoritative electrocardiographic criteria of normality in current general use. The implication is that electrocardiographic surveys will be misleading unless criteria of what is normal are revised and broadened.

Five Year Results in Treatment of Carcinoma of Uterine Fundus.—A consecutive series of 127 cases of carcinoma of the uterine fundus were analyzed by Scheffey and his co-workers. In 75 of these the five year end results could be surveyed. Four out of 5 women had passed their menopause. The average age of this group was 58.9 years, and the diagnosis was suspected correctly in 90 per cent because of the postmenopausal bleeding. In the premenopausal group the average age was 46.3 years. In 10 per cent carcinoma was not suspected.

It is among these younger women who have not ceased menstruating that irregular bleeding is too often regarded as benign in origin, and ill advised or inadequate treatment results. Abnormal uterine bleeding was the most significant and reliable symptom in 96 per cent of the entire series. The value of diagnostic curettage is apparent. Fibromyomas were noted in approximately 38 per cent of all patients treated surgically, and palpation suggested their presence in a number of irradiated patients. Previous pelvic operative procedures had occurred in nearly 30 per cent of all the patients. Carcinoma was thought to be limited to the uterus in 74 per cent of the patients when they were first seen, irrespective of the size of the uterus. Low grade lesions respond equally well to irradiation and to surgery, but it would seem that the survival rate in intermediate and high grade lesions is materially improved when irradiation has been a factor in the treatment, either singly or in combination with surgery. Prognosis based on the grade of malignancy alone is uncertain. The five year survival rate was 18.1 per cent with surgery alone, 40.5 per cent with irradiation alone and 38.4 per cent (corrected for uteri actually removed, 42.9 per cent) with surgery and irradiation. The authors are convinced that preliminary irradiation with radium, followed by complete operation eight to ten weeks later, is the treatment of choice for carcinoma of the fundus.

Treatment of Dysmenorrhea by Hypnosis.—Kroger and Freed applied the following procedure to 4 patients. Hypnosis was induced after rapport was established with the patient. This was characterized by a state of generalized hypersuggestibility. Suggestions were made in this state that the next menses might be free from pain or without excessive discomfort. Also suggestions were made that the next menses would be normal in all respects. Posthypnotic suggestions last about a month, and when repeated the desired effect may become permanent. All 4 patients were permanently cured. Only one treatment was necessary to bring about a permanent relief in 2 cases. Three to twelve treatments were necessary for the other 2 cases. Some cases of functional dysmenorrhea present a psychosomatic pattern which may be responsible for a lowered pain threshold. Because psychogenic factors contribute to the dysmenorrhea, they must be determined by an exhaustive study of the personality. The authors have utilized age regression with hypnoanalysis in 5 cases. The patient is regressed to a preadolescent age or reverted to the age prior to the onset of dysmenorrhea. The patient is then slowly reoriented to the present chronological age. The development of emotional conflicts, personality changes, inhibitions or harmful habit patterns can be discovered. Appropriate suggestions are then made toward their removal. After the patient's consciousness is reeducated by intensive psychotherapy under hypnosis, a cure may be effected readily. Hypnosis when used in these cases is only the means toward treatment, not the cure itself. It speeds up the analytic process. Of 9 patients treated, 7 were completely relieved of their menstrual discomfort following the use of hypnosis either by itself or with hypnoanalysis and age regression. One was partially relieved and the 1 failure was due to factors beyond the authors' control.

Studies on the Rh Factor.—Beginning in February 1941 and continuing for a period of sixteen months, Schwartz and Levine studied the bloods of selected patients to determine whether they were Rh+ or Rh−. Potent anti Rh agglutinins derived from mothers of erythroblastic infants now had become available. All serums were also tested for the presence of anti Rh or other atypical agglutinins. An attempt was made to examine the blood of each mother who had an unexplained stillbirth or neonatal death and of some mothers with various complications of pregnancy. The authors conclude that in most instances erythroblastosis fetalis is produced as a result of immunization of the Rh− mother by Rh+ fetal erythrocytes. The action of maternal anti Rh agglutinins on the susceptible fetal red cells is the source of the hemolysis in the fetus during intrauterine life. Among 162 consecutive stillbirths and neonatal deaths the incidence of erythroblastosis fetalis is somewhere between 4.4 and 8.2 per cent. Rh studies indicate that the incidence of erythroblastosis fetalis in this series is 100 per cent that heretofore given on the basis of clinical and postmortem diagnosis. In cases of intrauterine death occurring with in

advance of labor, as evidenced by fetal maceration, the incidence of erythroblastosis is somewhere between 16.6 and 29.1 per cent. Studies of a relatively small series of cases indicate that the Rh factor is important in the production of late but not of early abortions and that it is unimportant in the etiology of hemolytic jaundice, sicklelema, hydatidiform mole and ectopic pregnancies. While infants with erythroblastosis fetalis are often premature at birth, most causes of prematurity appear unrelated to the Rh factor. Proof for the possible relationship of blood incompatibility of the mother and her fetus to eclampsia and specific toxemia is still to be provided.

Androgen Therapy in Pelvic Cancer.—Beecham submitted a small group of patients with ovarian carcinoma (also two with carcinoma of the cervix) to androgen therapy. These cases were hopeless and it was felt that no harm could result from endocrine therapy. Although the final results in these cases were identical to similar cases in which androgenic therapy was not employed, the author is of the opinion that this method is definitely worth while. The pain experienced by the majority of these patients was almost completely relieved, and they were much improved as evidenced by their gain in weight. Such results cannot be expected from opiates and high voltage roentgen therapy. None of the cases demonstrated evidence of reduction in size of the neoplasm, nor were histologic changes found. The author thinks that androgenic therapy should be further tried in cases of this type.

Vagitus Uterinus.—A woman aged 35 had had previous deliveries. One was a breech delivery which resulted in a permanently atrophied arm and the second a high forceps delivery which resulted in a stillbirth. Ryder reports that she had been promised that the third delivery, unless it could be normal, should be by cesarean section. For this delivery she came to the hospital in active labor. The baby was small, with the head high at the pelvic brim in occiput posterior position. Labor progressed rapidly. It seemed as though delivery would be normal and quick, but the head did not descend. The cervix was found fully dilated with the head well engaged. Forceps were applied, but moderate tractions caused no advance. The forceps were removed and preparations for a cesarean section were made. With a stethoscope on the patient's abdomen the fetus could be heard crying loudly. When the crying stopped, the fetus could be heard breathing with gurgling respiration as though choking with fluid. It seemed probable that the fetus could inspire too much liquor amnii and it was considered wise to wait for the section. Breech extraction was performed and resulted in the birth of an undamaged baby which was soon revived and crying lustily. Reference to 131 cases of vagitus uterinus were found in the literature of various countries from 1546 to 1941.

Roentgenographic Aspects of Pulmonary Cavity Aspiration.—Oechsli and Kupka describe the roentgenologic aspects in 17 cases of pulmonary tuberculosis in which Monaldi's method of aspiration was used. All but two cavities were of the balloon type, and the most prompt results were obtained in these cases. The results in two type 3 cavities with probably

caseous walls were slow and poor. Behavior of the cavity wall in some patients appears to substantiate Monaldi's contention that the cavity wall in many instances is partially made up of compressed, airless alveoli, rather than pathologic material. An increase in dense shadowing over the part of the lung containing the cavity, noted by others using this method, appears to be due in part to localized pleural changes which may be associated with the high negative pressure produced in the cavity by this treatment. The state of the tract occupied by the catheter is best determined by body section roentgenography. This method of examination is also a prime requisite to determination of cavity closure.

Thiocyanate Goiter in Man.—Rawson and his associates direct attention to the goitrogenic effect of cabbage and other brassica plants and to the fact that the sulfonamides and thiourea-like compounds act as goitrogens. With the advocated use of soy beans in the modern diet, the liberal prescribing of the sulfonamides in clinical medicine and with widespread use of thiocyanate in treating hypertension, it becomes of practical importance to know whether such agents have any goitrogenic action in man. The authors report the development of goiter in 2 patients who received potassium thiocyanate for hypertension. A similar case was seen in consultation, and several were cited from the literature. Thiocyanate goiter is characterized by (a) hyperplasia of the thyroid, (b) symptoms of hypothyroidism, (c) exophthalmos (seen in 1 case), (d) low basal metabolic rate, (e) low blood iodine, (f) decreased urinary excretion of labeled iodine and (g) increased urinary excretion of thyrotropic hormone in the inactivated form. The theory is advanced that this drug blocks the formation of thyroid hormone by the thyroid and that the consequent lowering of concentration of active thyroid hormone in the blood stream causes stimulation of the anterior pituitary to produce an excess of thyrotropic hormone. This in turn causes thyroid hyperplasia but, because of the block, no increase in physiologically active thyroid hormone output. It is a hyperplasia of frustration. An excess of administered iodine may force the block and cause liberation of active hormone. Administration of thyroid bypasses the block and relieves the situation by substitution. Thiocyanate goiter can probably be prevented by prophylactic doses of iodine. Thiocyanate goiter can be relieved by the administration of thyroid even when thiocyanate administration for hypertension is continued.

Amyloidosis Complicating Tuberculosis.—Amyloidosis is a common complication of tuberculosis. Postmortem examinations of 143 patients with tuberculosis revealed amyloidosis in 53, or 39 per cent. This report is based on the 53 cases and on 26 patients with clinical evidence of amyloidosis and 100 per cent absorption of congo red in the Bennhold test. One hundred per cent absorption of the dye by the tissues within one hour is indicative of amyloidosis. A negative congo red test does not exclude amyloid disease. Albuminuria and casts antedated 100 per cent congo red retention in about one third of a group of 37 cases. Urine analyses in 143 tuberculous cases revealed that about 75 per cent of those who spilled albumin plus casts had amyloidosis. This is emphasized as a diagnostic criterion. Charts are presented in an attempt to visualize the prognosis of 58 tuberculous patients with amyloidosis, using the urinary aspects as connoting the probable onset of amyloidosis.

Almost 90 per cent were dead within two years after the development of amyloidosis. The nature of the underlying tuberculous lesion greatly influences the span of life in the amyloid phase. The oral therapy was a high protein diet, iron and diluted hydrochloric acid. Twenty-three also received parenteral therapy, which was chiefly liver extract. Objective improvement in the amyloid status was found in 4 patients who had arrested tuberculous disease. Adequate control of tuberculosis was probably the chief factor in the improvement. There was no evidence of anatomic regression of amyloidosis in 5 cases that came to necropsy.

Rheumatic Pneumonia.—Neuburger and his co-workers made pathologic studies on 63 consecutive cases of active and quiescent rheumatic fever in Denver. There were 8 cases of pulmonary inflammation which showed peculiar granulomas in the alveolar ducts and alveoli, focal alveolitis with necrosis, fibrinous exudation and hyaline lining membranes, arteriolitis, mononuclear cell exudation and septal cell proliferation. The term "Masson body" is suggested for the rheumatic pulmonary granuloma, which is considered to be an equivalent of the Aschoff body in the heart. Canadian authors expressed the opinion that the rheumatic involvement of the lungs they observed was related possibly to environmental conditions peculiar to Montreal. The studies of Neuburger and his co-workers indicate that the same type of rheumatic pulmonary change occurs elsewhere. It is of interest in this regard that Colorado has a high incidence of rheumatic fever. This is contradictory to the opinion that high altitude and dry, sunny climate, which prevail in Colorado, protect against rheumatic infection.

Salicylate Therapy in Rheumatic Fever.—Coburn attempted to determine whether or not salicylate modifies the inflammatory reaction which characterizes activity of the rheumatic process, to identify the active salicylate fraction and to develop a rational technic for the treatment of the rheumatic attack. He describes a simple method for the determination of the salicyl radical in oxalated blood and presents data on plasma salicylate levels in relation to dosage of sodium salicylate in rheumatic fever. Observations on the relation of rheumatic activity to the plasma salicylate level show that 20 patients maintained at 359 to 400 micrograms per cubic centimeter manifested a prompt and progressive subsidence of rheumatic inflammation and that 20 other patients with plasma levels below 250 micrograms per cubic centimeter continued to manifest an active inflammatory process. The intravenous administration of sodium salicylate is required to obtain a rapid rise in the

plasma concentration of salicylate to 400 micrograms per cubic centimeter or higher. A therapeutic technic for the use first of intravenous and later of oral salicylate is suggested for the rapid development and maintenance of plasma salicylate levels above 350 micrograms. The results of two years' experience with this technic show that none of 38 rheumatic patients treated with 10 Gm. of sodium salicylate daily developed valvular heart disease and that 21 out of 63 similar patients who received only small doses of sodium salicylate developed physical signs of heart disease. The observations suggest that a plasma salicylate level of at least 350 micrograms per cubic centimeter may be required to suppress the rheumatic reaction and that plasma levels below 200 micrograms per cubic centimeter may be sufficient to relieve symptoms while masking a progressive inflammatory process.

Anaphylactic Nature of Rheumatic Pneumonitis.—Rich and Gregory demonstrated that cardiac and arterial lesions having the basic characteristics of those of acute rheumatic fever can be produced experimentally as a result of anaphylactic hypersensitivity. The comparison of the peculiar lesion of rheumatic pneumonitis with that of the pneumonitis caused by sulfonamide hypersensitivity shows that the two are basically identical, and that both exhibit the primary capillary damage characteristic of focal anaphylactic reactions. This provides additional evidence in support of the view that the lesions of acute rheumatic fever may be anaphylactic in origin.

Diethylstilbestrol and Diethylstilbestrol Dipropionate in Prostatic Carcinoma.—Kahle and his associates report 7 cases of adenocarcinoma of the prostate, 6 proved by biopsy, which have been treated with diethylstilbestrol or diethylstilbestrol dipropionate since March 1940. These cases were reported in detail in February 1942, and 5 cases which could be followed are brought up to date in this communication. In 4 cases the improvement previously reported in the general health, relief of symptoms and local findings has continued to date. The fifth patient died of urinary sepsis and cardiac failure. In all 5 cases, including the fatal case, serial microscopic examination showed regression in the carcinomatous tissues. There was a regression of metastatic osseous lesions as demonstrated by serial roentgenologic examination in the single case in which such lesions were present and a regression of metastases to the lymph nodes in another instance. Massive doses of diethylstilbestrol and diethylstilbestrol dipropionate were used without ill effects except for transient gynecomastia in a single instance. In 1 patient who presented an apparent recurrence of the carcinomatous process a second course of treatment was as effective as the first in controlling symptoms and causing a regression of the neoplasm. The changes observed in stilbestrol treated carcinomas of the prostate, as compared to untreated carcinoma, are as follows: 1. In the untreated specimen the neoplastic cells present large vesicular nuclei, prominent nucleoli and granular, reticular cytoplasm. 2. In the first stage of regression there is a decrease in the size of the nuclei associated with condensation of the nuclear chromatin. Nucleoli are no longer visible, and mitoses are absent. Cytoplasmic vacuoles appear and are located predominantly at the bases of the cells. 3. In the second stage of regression the nuclei are pyknotic. The cytoplasm is practically clear and the cell membranes have ruptured, with resulting coalescence of vacuoles. With the rupture of all the cell membranes, the pyknotic nuclei and the fragments of the membranes are clustered in the centers of the acinar spaces. 4. In the next stage of regression, clear acinar spaces contain only remnants of pyknotic nuclei. 5. In the final stage only stroma, consisting of smooth muscle and fibrous tissue, remains. Accumulations of lymphocytes and macrophages and deposits of brown pigment are present in some parts of the stroma.

Adrenal Heterotopia, Rests and the So-Called Grawitz Tumor.—O'Crowley and Martland encountered adrenal-renal heterotopia with the adrenal glands (complete heterotopia) or a considerable portion of them (partial heterotopia) beneath the capsule of the kidneys and with no adrenals in their normal position eight times in the routine examination of 5,000 consecutive bodies. The explanation of this anomaly, which in their experience is always bilateral, is unknown. As the renal capsule is said to be completed at a time in early fetal life when the adrenal cortex is far distant, it would seem that a mechanical displacement is impossible. It suggests that either

embryologic data are incomplete, that exceptions occur or that pluripotent cells exist which can form either renal parenchyma or adrenal cortex. Contrary to some authorities, this anomaly seems to have no effect on the life of the individual. It neither shortens life nor predisposes to infections, tuberculosis or debilitating diseases. No endocrine disturbances were observed. The recorded high incidence of status lymphaticus with this anomaly is not borne out in the cases seen by the authors. In adrenal-renal heterotopia the surgeon in performing a nephrectomy would unwittingly remove the adrenal. The authors have never heard, however, that this has been done. Since the heterotopic adrenals are hypoplastic and, in addition, contain no medulla (or scant medulla in extracapsular portions only) such an operation might cause symptoms suggesting adrenal insufficiency. The demonstration that the entire adrenal cortex, or large portions of it, may be found beneath the renal capsule remaining on the kidney after decapsulation, and the finding in some of these cases of many small, isolated bits of cortical tissue near these subcapsular adrenals, but scattered over the surface of the kidney, greatly strengthens the opinion held by many pathologists that the so-called adrenal rests are cortical adrenal tissue which have become misplaced during development. It is reasonable to assume, therefore, that some renal hypernephromas may arise from such misplaced cortical adrenal tissue.

New Method of Giving Potassium Iodide.—Garfield describes the use of potassium iodide in the form of enteric coated pills. The enteric coating on these tablets does not dissolve until it comes in contact with the bile in the intestinal tract; it is insoluble in alkaline or acid solutions alone. The enteric coated pill was given in 12 cases of syphilis in varying amounts. The 12 patients responded well, and none complained of a gastric upset. Three patients evidenced idiosyncrasies to the drug. In view of the lack of gastric disturbances and the accuracy of dosage, further trial of this method of administering potassium iodide is recommended.

Amputation with Refrigeration Anesthesia.—Massie states that with refrigeration, not freezing, tourniquets may safely be left on for many hours. Anesthesia produced by the combination of tourniquet and low temperature of the ice pack is complete. There is no shock during or following the amputation. Infection is completely controlled in the postamputation stumps by continued cold packs, though there is experimental evidence that the tissues may be more susceptible to infection after the temperature is restored to normal. The experimental and clinical evidence emphasize the menace of applying heat to tissue with a reduced and inelastic blood supply. The author used the refrigeration anesthesia in 14 cases chiefly for amputations for diabetic and peripheral vascular lesions. The mortality for such amputations was formerly as high as 65 per cent. The ice and ligation method reduced this to 15.5 per cent in 45 patients who underwent 62 operations. The mortality for thigh amputations in this series was 13.3 per cent.

Treatment of Intertrochanteric Fractures of Femur.

Johnson states that analysis of the causes of death in patients with intertrochanteric fracture of the femur at St. Louis City Hospital revealed that pneumonia accounted for from 39 to 53.4 per cent of the fatalities. Decubitus ulcers have always been a major problem in the care of these patients. To overcome some of these complications, the use of a hanging cast has been tried. In 50 cases treated by this method the mortality rate has been reduced from 39.3 to 18 per cent and the duration

of hospitalization from 84.7 days to 62.3 days. In order to prevent pressure sores and peroneal nerve paralysis with accompanying foot drop a Steinmann pin is inserted through the distal end of the femur and incorporated in the cast. No local infection of soft tissues or bone injury has resulted from the Steinmann pin. The cast is applied with the knee in 30 to 40 degrees of flexion. As soon as the plaster is sufficiently hardened, from 20 to 35 pounds of traction is applied through an overhead pulley at the foot of the bed. The line of traction is similar to that used in a Hodgen splint. The traction is used only while the patient is in bed, the weight of the cast acting as traction while the patient is in a wheel chair or up on crutches. One to three days after the application of the cast, each patient is placed in a wheel chair for two to six hours daily. The casts were removed after an average of 43.4 days. Complications, such as pneumonia, decubitus ulcers, stiffness of knees and ankles and weakness from lying in bed, were less frequent. The reductions have been as good as the reductions obtained by other methods. There were no instances of nonunion.

Dermatome Pattern Graft in Reconstruction of Hands.

—For the reconstruction of injuries to the cutaneous covering of the hands the free skin transplant holds advantages over the prolonged pedicle flap operations. The introduction of the dermatome has resulted in a method of obtaining uniformly large grafts of a predetermined thickness with sharp straight edges, more suitable for smaller reconstructions than the razor graft. Kanthak describes a method of utilizing the dermatome in preparing grafts of a specific pattern for reconstruction of extensive injuries of the hands. This procedure consists in the removal of a split graft with the dermatome, cutting a pattern of the area to be grafted and transferring the pattern to the dermatome drum, where the outline is cut on the drum. The graft is subsequently transferred to the recipient area, where it is sutured and dressed in the customary manner. The method represents a combination of full thickness and split thickness grafting and is especially suitable for large areas of irregular outline. Since the donor site requires no additional surgery for closure as does the full thickness grafting technic, this procedure simplifies the problem of restoring areas of considerable size and complicated design. This method is of value in treating keloidal areas by complete excision and skin grafting.

Nutritional Deficiency in Etiology of Menorrhagia.

According to the Biskinds the liver of a rat loses its ability to inactivate estrogen in vitamin B complex deficiency. Observations on 104 patients provided evidence that menorrhagia, metrorrhagia, cystic mastitis, premenstrual tension and probably uterine myomas as well are caused by failure of the liver to inactivate estrogen owing to deficiency of factors of the vitamin B complex. Of 39 patients who were observed primarily because of the presence of lesions of nutritional deficiency, 37 had a history of one or more conditions related to excess estrogen. Of 52 patients whose main complaint was one of the latter conditions and who were examined for evidences of nutritional deficiency, every one had signs or symptoms or both characteristic of B avitaminosis. Prompt and often dramatic responses were obtained in the gynecologic conditions with vitamin B complex orally, parenterally or by both routes.

Accurate Diagnosis of Influenza and Acute Catarrhal Fever.—There has been a tendency since the 1918-1919 influenza epidemic to use carelessly the diagnostic designation "influenza." A wide variety of febrile respiratory conditions and even many vague gastrointestinal disorders are erroneously termed "the flu." In order to counteract this tendency the Navy introduced into its medical terminology the designation "catarrhal fever, acute" for all forms of influenza-like respiratory conditions. However, catarrhal fever has come to serve as an even more inclusive "catch-all" diagnosis than the term which it was meant to replace. From December 1942 to May 1943 the medical officers of Laboratory Research Unit No. 1 observed several hundred patients with a diagnosis of catarrhal fever, acute, at a large west coast naval dispensary. All these cases could have been given a more specific designation. Included under the diagnosis were found cases of influenza, atypical pneumonia, lobar pneumonia, septic sore throat, acute follicular tonsillitis, acute laryngotracheitis, acute bronchitis, rubella and the common cold, the latter of both afebrile and febrile types. The only cases justifying the nonspecific designation of catarrhal fever were the cases of common cold with fever—the "febrile catarrh" of the English writers. The grouping of such a wide variety of diseases under one heading leads to both diagnostic and therapeutic carelessness. Influenza is not merely nosologically distinct from other respiratory infections but is due to a specific agent, the influenza virus. This virus cannot be isolated from any of the other "catarrhal fever" group of respiratory diseases. The accuracy of the diagnosis of influenza can be put to the test of virus isolation. Influenza may be confused with the febrile type of common cold (acute catarrhal fever or febrile catarrh) and with streptococcal tonsillitis (septic sore throat).

Treatment of Burns on Board a Hospital Ship.—Kern and his co-workers report 360 cases of burns incurred by naval and military personnel. Burns constitute an important group of casualties in naval warfare, and preparedness for their treatment must include a store of supplies and an organized and trained personnel. In order to distribute the working load the treatment of burns should be assigned to the medical and not to the surgical service. Since patients with burns die not of their burns but of shock, toxemia or sepsis, the first step is to prevent or treat these complications. Pressure dressings can prevent to some degree the development of edema as well as reduce an existing edema. Particularly is this true in burns of the extremities over which an elastic bandage can be applied. Shock must be treated by adequate amounts of plasma, the

dosage being based on frequent hemoglobin determinations. The use of morphine in the relief of pain calls for an initial dose of not over $\frac{1}{2}$ grain (0.032 Gm.) subsequent doses of not over $\frac{1}{4}$ grain (0.016 Gm.) and the meticulous recording of each dose given, on a tag attached to the patient. Toxemia is most effectively met by an adequate fluid and salt intake. A prime requisite in guarding against infection of burns is the use of an aseptic technic in dressing, including the masking of attendant personnel. The preparation of the burn area for the local treatment calls for simple cleansing (liquid petrolatum and sterile cotton waste to remove fuel oil; plain soap and water) and a minimal débridement (cutting away blisters). The method of local treatment best suited to naval conditions is one that is applicable to all burns. Tannic acid, paraffin wax and triple dye are not suitable. Tannic acid must not be used on the face, ears or hands. Not one of the methods mentioned is applicable to an infected burn or in the preparation for skin grafting or to a patient with wounds or fractures. Sulfathiazole, either in 3 per cent ointment with a water soluble base or as a dusting powder with wet saline dressings, meets all requirements. Skin grafting should be done early to prevent scar formation. Many burns could be prevented in naval actions by full clothing at battle stations, by the use of antiflash gear that has been fireproofed and by the constant availability of gloves for use in case of fire or sliding down ropes, since burns of the hands are responsible for the longest periods of disability.

Joint Pain in Young Adults.—Martin made a survey of 106 recruits admitted to his hospital with the complaint of joint pain. All were white males between the ages of 17 and 24 years in preliminary naval training. All had passed normal physical examinations not more than three months prior to admission. With the exception of 5, all were examined and studied. Ninety-seven cases (92 per cent) were clinically diagnosed as rheumatic fever. Eighty-five (80 per cent) of the total presented evidence of cardiac damage. Rheumatic fever must be kept continuously in mind in all cases of joint pain in young adults. It must be considered as the causative factor until ruled out by careful observation and cardiographic studies.

Tropical Eosinophilia.—Weingarten described under the term tropical eosinophilia an endemic disease which is apparently widespread in the coastal regions of southern India, 81 cases having been observed by him during five years' practice in Bombay. It is characterized by a chronic paroxysmal cough, frequent attacks of asthmatic breathing, weakness, listlessness, loss of weight and appetite, and leukocytosis ranging from 20,000 to 60,000, apparently due chiefly to an increase in eosinophils. The onset of the disease is gradual with a low grade fever, splenic enlargement, apathy and weight loss. After about a week, hacking paroxysms of coughing begin, usually occurring in the early morning hours and frequently associated with moderately severe asthmatic attacks resembling true asthma in their response to adrenergic drugs. Physical examination at this stage reveals the constant presence of numerous sibilant and sonorous rales throughout the lungs and prolonged expiration. After two to three weeks the fever subsides but the remaining symptoms persist and become chronic, lasting for a period of years if untreated. Emerson reports the history of an ensign aged 30 who developed the typical symptoms of tropical eosinophilia eight months after his return from India. A rapid disappearance of all evidence of the disease followed the oral administration of carbarsone. It seems probable that the man acquired his disease during his stay in India but that it remained latent until his powers of resistance were diminished by a severe intercurrent infection. When he had sufficiently recovered from the more severe symptoms of his liver abscess it became possible to recognize the milder signs of tropical eosinophilia. With increasing contact between the United States and India it is likely that more cases of tropical eosinophilia will turn up in this country. Since little is known of its etiology, epidemiology or total geographic distribution, there is no reason to think that it may not be widespread in tropical climates. In spite of the failure thus far to find an etiologic agent, the remarkable therapeutic effect of arsenic points toward a spirochetal or protozoan infection of some sort.

Thymectomy for Myasthenia Gravis.—Nellen reports the case of a nurse, aged 23, who had myasthenia gravis. She responded to treatment with neostigmine, but her requirements rose so that after two months she needed 225 Gm. daily. Removal of a part of the thymus effected a slight improvement, but because her condition deteriorated again in spite of neostigmine treatment the remaining thymus was removed. Neostigmine medication had to be continued for a number of weeks after the operation, but gradually she needed less and less and finally felt strong without it.

*Mycotic Ear Infections at an Advanced Allied Base. E. L. Davis.—p. 437.
Study of Treatment of "Tropical Ear." H. Earnshaw.—p. 438.

Myotic Ear Infections.—According to Davis, fungous infection of the external auditory canal is a fairly prevalent condition in tropical regions. He reports observations on 22 patients who were examined and treated during June and July 1943. Three stages of this disorder can be observed. In the first stage the ear feels sore and tender to the touch; chewing may be painful. The auditory canal often contains soft semi-fluid wax and debris of flecks of a white foamy substance. This stage was not seen in this series of cases, since the soldier usually presents himself in stage 2 or stage 3. In the second stage, which was seen in 16 of the patients, the ear is tender and chewing is painful. The canal is coated and sometimes completely blocked with soft, moist, sebaceous-like detritus, often with a greenish tinge due to a secondary infection with *Bacillus pyocyaneus*. After the ear has been syringed the canal wall is found to be red, with excoriation of the epithelial lining. The drum is not commonly affected. In the third stage the canal is swollen, often obliterated and very painful. The pain is worse at night. Sometimes when the swelling subsides an otitis media is revealed. All patients had a moderate pyrexia. In the initial stages the ear was syringed and swabbed with alcohol to dry out the canal. Glycerin and ichthammol (10 per cent) tampons were inserted. Subsequently the canals were swabbed with alcohol once a day and painted with carbolic fuchsin. When the canals were still "moist" after treatment with carbolic fuchsin, sulfathiazole powder was insufflated and the condition rapidly dried up. The six patients in the stage 3 category were admitted to the hospital. Apart from routine treatment, analgesics were given and heat was constantly applied by hot water bags. The average duration of treatment was seven days for cure. In eleven of the specimens submitted for pathologic examination, a fine mycelium was identified (trichophyton). A number of the patients had coexistent mycotic skin disease. Transmission of the infection to the ear may have occurred by towels.

*Role of Sugar in Physical Exertion. R. M. Du Pan.—p. 196.

Role of Sugar in Physical Exertion.—Du Pan studied the role of sugar in physical effort during eighteen months in military service. In subjects who are in a normal status of training the sugar reserves are sufficiently great to permit exertion of long duration without the blood sugar going greatly below normal. He mentions several investigations, which show, on the one hand, the uselessness of "doping" with sugar during violent but short exertion and, on the other, the role of foods high in carbohydrates during the days preceding an effort of long duration. The physician can recommend to his patient foods rich in starches on the day preceding great exertion in order to permit the formation of sugar stores in the body. He should advise against excessive consumption of meats, commonly believed excellent during great exertion, because meat is chiefly composed of proteins, which, while giving a feeling of vigor, have a weak calorific power and produce wastes which impede the circulation and augment uremia.

Archivos Argentinos de Pediatría, Buenos Aires

14:263-350 (Oct.) 1943

- *Infantile Encephalitis in City of Cordoba (Argentina). J. M. Valdes.—p. 263.
Pathologic Anatomy of Epidemic Encephalitis Observed in the City of Cordoba. A. Ferraris.—p. 329.

Infantile Encephalitis in Argentina.—In the autumn and summer of 1940 and 1941 an epidemic of meningoencephalomyelitis occurred in Cordoba, Argentina. Although isolated cases had previously been observed, it was the first epidemic of encephalitis to be recognized in Argentina. Eighty cases were observed by Valdes in the University Hospital. The incidence was higher in infants and young children. Clinical features were variable. As a rule, the onset of the disease was acute, characterized by high fever, headaches, convulsions, delirium, unconsciousness, agitation, meningeal signs and coma. In many cases the onset of sensory and motor disturbances was preceded by or associated with gastrointestinal symptoms, such as diarrhea, vomiting and abdominal pain. Especially in infants the gastrointestinal symptoms often overshadowed the nervous disturbances, misleading the diagnosis. Spinal fluid examination in these cases was decisive. In 13 cases the initial symptoms were less sudden and severe, and manifestations referable to the nervous system developed more slowly. A most striking sign of the disease was profound coma associated with sensory and motor abnormalities. Paralysis were usually of short duration and irregular distribution. Bulbar and cerebellar involvement were the rule with convulsions, athetosis, palatal and facial paralysis and terminal respiratory paralysis. Tendon reflexes were sometimes unobtainable, often accentuated. Abdominal reflexes were, as a rule, absent. Cerebrospinal fluid changes were invariably present in the first days of the disease, being characterized by lymphocytosis, high total protein content and positive Pandy test. The prognosis of the disease was very poor. Of 67 patients acutely ill 40 per cent died and 16 per cent displayed severe sequelae such as hydrocephalus, epilepsy and mental deterioration. In the whole group only 44 per cent appeared to have recovered completely without after-effects. Postmortem examination revealed venous congestion and edema of the brain, nonpurulent subcortical focal encephalitis with lymphocytic perivascular infiltration and extensive glial proliferation. There were also acute passive congestion and toxic changes in the liver, spleen, kidney and gastrointestinal tract. Bacteriologic tests, inoculation of the spinal fluid of guinea pigs, blood cultures and cultures of the spinal cord and the brain all yielded negative results. Neutralization tests with convalescent serums were negative for virus of the Japanese type B, equine encephalomyelitis of the eastern, western and Argentine (Rosenbusch) strain as well as for the St. Louis virus. The disease could be transmitted by inoculation of brain emulsion into white mice and was then transmissible from mouse to mouse. The pathogenic agent was a filtrable virus. The epidemic outbreak in human beings occurred simultaneously with a very severe epizootic among horses and was followed by an identical epizootic in fowls.

Book Notices

Principles and Practice of Rehabilitation. By John Elsele Davis, M.A., Sc.D. Cloth. Price, \$3. Pp. 211, with 8 illustrations. New York: A. S. Barnes & Company, Inc., 1943.

With the increasing interest in rehabilitation, a short textbook on the subject should have a large reading demand. Most of the current thought of rehabilitation is concerned with the reconditioning of World War II veterans. Neuropsychiatric causes constitute the largest number of medical discharges of soldiers and sailors at present. Dr. Davis carefully reviews the different psychiatric entities commonly found among veterans of World Wars I and II. A chapter on the psychologic approach of mental disease and another chapter on the theories of reeducation provide an excellent back drop for the second half of the book, which discusses psychotherapy.

A general review of many aspects of psychotherapy are given in the last four chapters. The use of occupational therapy, music, drama and education are given in outline. Suggested programs and board aims of many workers in these fields are given. It is regretted that the author did not give the results of his own experience at the Veterans Administration Facility, but relied to so large an extent on the results of others.

Mention is not made of the rehabilitation of diseases and injuries other than neuropsychiatric entities. In avoiding the large fields of reconditioning battle casualties, tropical diseases, postoperative surgery and infectious diseases Dr. Davis might well have limited the title of his book to "Principles and Practice of Rehabilitation of Neuropsychiatric Entities." On the whole the book is well written and informative, and it should be of value to those engaged in the reconditioning of neuropsychiatric patients.

Surgical and Germ-Free Techniques . . . Their Application to Experimental Biology and Medicine . . . A Symposium. Edited by James A. Reyniers, The Laboratories of Bacteriology, University of Notre Dame, Notre Dame, Indiana. Fabrikoid. Price, \$5. Pp. 274, with 94 illustrations. Springfield, Illinois & Baltimore: Charles C Thomas, 1943.

This book, in two sections, is a collection of the papers read in a symposium held at Notre Dame in November 1939 to present in concise form the latest information in two specialized fields. The first section is on the science and practice of microdissection and microinjection with chapters devoted to the design of machines for use in bacteriology, the application of surface chemistry to the study of living cells and the application of micrurgy to botany, with special reference to phytopathology. The second section, devoted to germ free methods, takes up first the problem of isolation and the elimination of contamination, describing in detail the development of the machines for rearing and working with germ free animals, with a description of the technics employed, using a variety of animals and fowl. One chapter is devoted to the use of the mammalian fetus as an experimental animal in bacteriology, virology and immunology, with the technic employed, describing the limitations and certain results obtained. One chapter is devoted to the germ free culture of certain invertebrates and describes several technics as used for protozoa, nematodes and insects. Another chapter considers the application of such germ free methods to botany, with particular emphasis on its application in the study of the physiology and pathology of higher plants, where "aseptic technic is highly desirable if not absolutely essential." The last chapters are devoted to the control in nurseries of cross infections transmitted by way of the air. A variety of mechanical and ultraviolet radiation barriers are described and are used in combination with air conditioning installations for adequate ventilation. Bacteriologic studies showing comparative results for various types of barriers both with and without air conditioning are given. These cover both the general bacterial level under given conditions of occupancy and the transmission of bacteria from a given point of dissemination to all parts of the nursery. All studies are bacteriologic, and no clinical observations are recorded. In addition to the concise presentation of some particular phase of the subject, each chapter closes with a bibliography. For any one interested in these special fields, this book should prove valuable both for the subject matter and for the bibliographies.

Endocrine Disorders in Childhood and Adolescence. By H. S. Le Marquand, M.D., M.R.C.P., Physician, Royal Berkshire Hospital, London, and F. H. W. Tozer, M.D., M.R.C.P., Sometime Clinical Assistant, Royal Berkshire Hospital. Cloth. Price, 15s. Pp. 298, with 49 illustrations. London: Hodder and Stoughton, Limited, 1943.

Endocrinology is a much disputed topic; most books on this subject present at least a few ideas which will be hotly contested. This publication is no exception. Nevertheless for a small volume it offers interesting reading and should elicit some sound practical treatments by those who will apply endocrine preparations intelligently. In the United States the present edition will not displace other well known works, but it will be a useful addition to the libraries of teachers and others who follow closely published literature as it provides a list of commercial sex hormone preparations sold in England. Since many journals do not have a policy demanding that the official, chemical or common name be included to identify a drug which may be mentioned in a communication, the reader is often at a loss to know whether such names as Erugon, Polyansyn, Lutocyclin and Aristostab are androsterone, anterior pituitary, corpus luteum or gonadotropic preparations. This book will provide also useful information on the treatment of endocrine disorders in children.

The Arthropathies: A Handbook of Roentgen Diagnosis. By Alfred A. de Lorimier, A.B., M.A., M.D., Colonel, Medical Corps, United States Army. Cloth. Price, \$5.50. Pp. 319, with 678 illustrations. Chicago: Year Book Publishers, Inc., 1943.

With emphasis on a visual presentation, Colonel de Lorimier carefully and systematically leads the reader through the impressively large field which comprises the arthropathies. These he divides etiologically into closely related groups, such as those associated with stress, the osteoarthropathies, or a second, the true arthritides, due to protein reactions, toxins or bacterial invasion. Chapters are expanded only moderately beyond outline form, yet all essential points seem to be presented and clearly stated. Through use of eye catching subdivisions and a uniformity of presentation in each chapter, salient features between any two or a group of lesions are easily compared without need of extended reading. Each brief chapter, covering an arthropathy, begins with a list of synonyms; then follow the roentgen criteria both in early and in later stages with—importantly—attention being drawn to early soft tissue reactions which may give a clue to diagnosis before any bone changes become visible. Next come the corroborative roentgen findings, concise statements on incidence, age, sex, sites of usual involvement, finally statements as to history, accompanying physical findings, clinical course, even the laboratory findings when significant. The bibliography at each chapter end is well selected and adequate. There is an abundance of well selected and uniformly good illustrations selected not only from the writer's own large teaching collection but also from those of his associates and colleagues throughout the country. These are presented in their much more satisfactory form as reproductions of negatives rather than positives. Helpful placement of numerous arrows shows the diagnostic roentgen findings in each case, though the excessive length and tortuosity of the arrows somewhat offend the eye and mar the films.

Man in the Air: The Effects of Flying on the Human Body. By Herbert S. Zim. Cloth. Price, \$3. Pp. 332, with drawings by James MacDonald and photographs. New York: Harcourt, Brace and Company, 1943.

This is an excellent presentation of the topic of aviation physiology broadly interpreted. The writing is directed to the nontechnical reader, but the author is eminently successful in presenting the results of modern research and new technological developments in such a lucid manner that no intelligent reader need feel completely baffled. The book consists of twenty-two chapters and has over three hundred pages, but good typography and many illustrations in the text contribute to its readability. There are over fifty full page reproductions of photographs, which are in general well selected and are accordingly valuable additions to the text. Drawings and diagrams are used extensively. The author commences his book with short chapters on the atmosphere and on bodily functions. Chapters follow in which the problems of temperature and acrobolism are discussed and modern protective devices are described. The effects of high acceleration are described, and the special functions of

which time the crusts may be removed with cotton tipped probes. A little irrigation may again be necessary to remove the more adherent crusts. The mucosa is now thoroughly massaged with Mandl's pigment and the treatment is finished with a liberal spraying of warm camphor, menthol and petrolatum solution. As an alternative to Mandl's pigment (iodine 0.3, potassium iodide 0.6, glycerin to make 30), since it is best to rotate the various paints, Peruvian balsam may be used. Other solutions that may be painted or massaged into the mucosa are olive oil, thymol 1:10,000, resorcinol 1:200, phenyl salicylate 1:1,000 and sanitas fluid 1:50.

When ozena is present a spray of solution of formaldehyde U. S. P. diluted 1:100 preceded by cocaineization is often effective, as is the massage of "scarlet red emulsion" at the conclusion of a treatment.

Nasal packing for thirty minutes with simple syrup followed by irrigation with isotonic solution of sodium chloride is another line of therapy, while painting the nasal mucosa with a 1 part of zinc chloride to 30 parts of glycerin following nasal irrigation is another approach. Cotton plugs saturated with isotonic solution of sodium chloride are inserted into the nose sufficiently large to obstruct half of the lumen of the nostril and kept in situ for several hours or strips of ribbon gauze medicated with iodoform, sanitas, ichthammol or boric acid and wrung out of sterile water will be found of value.

All these measures indicate that a short course of cleansing, painting and packing should be meticulously carried out in the office several times a year while the patient continues to carry out his instructions at home.

Vaccine therapy has not proved successful. The several operative procedures that are known at the present time are paraffin injections, ivory implantation, the Lautenschlager operation and the Halle operation.

TESTING FOR SCHIZOPHRENIA

To the Editor:—Is there any connection between the Bárány test and schizophrenia? Is a negative Bárány test typical for schizophrenia? If not, does a negative result merely point to an organic base for the projection mechanism in schizophrenia? Where would you locate the seat of this projection mechanism, if any? In clinical psychiatry can the association test be regarded as a valuable help in the differential diagnosis of schizophrenia, psychoneurosis and manic-depressive psychosis? In a questionable case can one rely on this test for final diagnosis? Do you think that this test should play a major or decisive role in securing the proper diagnosis?
M.D., North Dakota.

ANSWER:—There is no definite relation between the Bárány test and schizophrenia. However, some authors have described postural reflex changes to body rotation as characteristically altered in some schizophrenic patients (Schilder, Paul: *Mind: Perception and Thought in Their Constructive Aspects*, New York, Columbia University Press, 1942).

The association test is a useful psychologic test in clinical psychiatry. The differential diagnosis of schizophrenia, psychoneurosis and manic depressive psychosis is best made on the basis of the history, the complete neuropsychiatric examination and careful evaluation of the psychodynamic factors. It would be advisable not to rely on the association test as the most important diagnostic aid.

Work on the basis of schizophrenic projection mechanisms has been done by many. The following references are recommended:

GROWING BREWERS' YEAST

To the Editor:—Will you be so kind as to give me the formula for a culture medium suitable for growing brewers' yeast? Many of the culture mediums produce a product with a very foul smell. The culture mediums used by brewers produce a pleasant smelling product.

James L. Crawford, M.D., Laredo, Texas.

ANSWER:—The best culture medium for growing brewers' yeast is brewers' wort, which may be prepared as follows: A corn mash is made by adding 240 Gm. of corn grits to 1,200 cc. of tapwater. Autoclave for one hour at 15 pounds, then cool to 70 C. Malt mash: Three hundred and sixty Gm. of ground barley malt is added to 2,000 cc. of water and held at 40 C. for one hour. It is then heated in a water bath to 70 C. and

added to the corn mash. Continue heating at 69-72 C., with stirring, until all the starch has been converted, using hundredth normal iodine solution as indicator. Strain the liquid from the coarse mash through a cheesecloth and autoclave it for thirty minutes at 15 pounds. Filter through paper and cool to 45 C. (leave in refrigerator over night), then filter out the cold fraction precipitate. Adjust the specific gravity to 1.04 and the pH to 5.3. Divide into flasks in appropriate quantities for storage and sterilize in autoclave. For plates or slants add 1.6 per cent agar to the wort.

If the wort is obtained at a brewery it should be drawn before the hops are added and should then be treated as mentioned after straining through cheesecloth.

Inoculate with about 3 Gm. of moist yeast per liter of wort and incubate at room temperature. The yeast crop will be greatly increased if a current of sterile air is passed through the culture during incubation.

EXTENSIVE TONSIL OPERATION

To the Editor:—During a tonsillectomy all the mucous membrane was dissected from the base of the tongue between the circumvallate papillae and the base of the epiglottis and from one side of the pharynx to the other. I never heard of such a procedure. I should like an explanation and comments. Does it cure allergy and asthma? Is it fair to the patient to refer to this procedure as getting all the lymphoid tissue in the throat (this is impossible) or to say that the lingual tonsil is removed (this is ambiguous); the patient understands neither. The results are undesirable, as any one might anticipate. Should not this possibility, or certainty, and the fact that the operation is new and controversial be discussed with the patient before doing it? There is no question of a suit; the time for this has passed. Such happenings are far too common, and I think some publicity and warning would do good to the profession at large both as to the procedure and as to the description, which quite naturally deceived the patient.
M.D., Ohio.

ANSWER:—This query is difficult to answer, as some of the facts cannot be verified and because the type of operative procedure described cannot be accurately identified. It may be said at the outset that no type of tonsil operation will cure asthma or other allergic states. The removal of diseased tonsils may improve the general physical condition of a patient suffering from those conditions, but no more could be anticipated.

There is an operation called expanded tonsillectomy which has been described in detail by Thomas R. French in Jackson and Coates's textbook on diseases of the ear, nose and throat. The procedure in question may not be the one advocated by French, but it may be useful to say a few words about the latter because of some resemblances between them. This operation aims not only to remove when necessary diseased faucial tonsils but developed lymphoid tissues below and between the two faucial tonsils. The extra tonsillar lymphoid tissues include what are commonly called the lingual tonsils and what French calls the lymphoid apron or: the base of the tongue and behind the circumvallate papillae.

This operation, while not practiced widely, has been recommended by reliable specialists and accepted for description in a textbook edited by men of the highest standing.

If the procedure described in the query is the same as the so-called expanded tonsillectomy and was properly performed, there should have been no undue after-results. Of course the patient should have been informed that this was not the usual type of tonsillectomy. The fact that an operation is new, however, or not widely practiced, should not be held against it; it needs only to be done with discrimination and skill, and no improper claims are to be made for it.

UMBILICAL HERNIA IN INFANTS

To the Editor:—In a recent article on the subject of umbilical hernia in infants, the statement is made that "the tongue and slot strapping has proved most effective and is the easiest type of strapping for a parent to apply successfully at home." I have always strapped these hernias with 2 or 3 inch width adhesive after invaginating the navel between lateral folds of tissue. If the "tongue and slot" procedure differs from this method I would appreciate learning the details.

J. Pancoast Reath, M.D., St. Davids, Pa.

ANSWER:—The purpose of strapping umbilical hernias is, of course, to maintain constant reduction. Details as to how this can be done can hardly be given dogmatically. If simple strapping with 2 or 3 inch wide adhesive after invaginating the navel between folds of skin has given satisfaction in maintaining reduction, this may be continued by those who have obtained good results by this method. The writer's interpretation of the "tongue and slot" procedure is as follows: A segment of tongue depressor is placed vertically and on edge over the umbilical hernia and pressed downward. This brings the skin on each side together over the slotlike depression made by the invaginated segment of tongue depressor, and adhesive straps are applied to maintain the reduction.

MEDICAL EDUCATION TODAY

REPORT OF CHAIRMAN OF THE COUNCIL ON
MEDICAL EDUCATION AND HOSPITALS

RAY LYMAN WILBUR, M.D.

STANFORD UNIVERSITY, CALIF.

These are great days for medicine. On all sides we are seeing the benefits of scientific medicine, of medical research and of good medical education. Procedures in the prevention of disease are being put into effect for millions of men and women in uniform. The deserts of Africa and the jungles of the South Seas have become new hazards for our armies—hazards that would have been almost prohibitive without an understanding of yellow fever, typhoid, dysentery, malaria and other diseases due to organisms that can live in our bodies and destroy or damage them. New procedures for the prevention and cure of infections, new technics in surgery and new methods of classifying men into groups for different types of national service all depend on the men and women trained in our medical schools and hospitals. Nutrition has become a mass operation under scientific guidance. Everywhere we turn in our civilization under the present strain of war we find science and the trained man and woman giving indispensable service.

Since this is as true of our enemies as it is of us, there can be no letup in our efforts to know all that is known and to seek to know more. There is a premium on research such as we have never seen before.

How wonderful it is to realize that we live under the universal laws of nature. When once known to us, these laws can be depended on always to play the game square. Medicine and magic have been completely divorced. The variable and unpredictable operation of the central nervous system remains our least understood area of knowledge; but even in the fields of the mind we are sensing the beginnings of scientific procedures. Through a vast volume of words, phrases and speculations occasional shafts of light are showing. We are beginning to see how environment and changes have followed us through our evolutionary rise out of the sea.

As our knowledge and experience grow, so must our educational methods change and develop. Just now medical education is under pressure, with continuous session, with modified courses, with shortened hospital training and with many professors absent on the battle

fronts of the world. Fortunately the whole structure of medicine has been held together. So far the frame has not changed materially, but there is no likelihood of our going back to many of our old ways. As practical experience has brought about the discarding of much old therapeutics and old thinking, so must medical education discard freely in order to make room for the new.

Medicine based on pills and potions is becoming obsolete. The new physiology, with the help of physics and chemistry, has taught us many ways to deal with the living body that were only dreamed of a decade ago. Blood plasma is now a part of our everyday language. Biologic thinking is replacing empiricism. The last war is said to have put orthopedic surgery on its feet. This war may well do the same for physical medicine. Those treatments involving the use of heat, cold, water, electricity, movement and massage have striking biologic responses, including effects on psychic reactions, more potent than many of the drugs gathered through many centuries by trial and error.

The medical student of today needs to have his instructors fan over the grist of the past and select carefully those subjects on which he can best spend the limited period of his training. Historical sequence is important and entertaining but ought not to lead to engorgement of the student's mind with the trash or near trash of the past. As I have said before, on other occasions, time is the only real possession of the doctor; certainly it is the one thing that ought not to be wasted for the embryo doctor or intern.

Along with the revolutionary changes in medicine itself we are undergoing rapid and even kaleidoscopic social changes in which medicine is involved. There is no escape from the steady growth of new phases in the practice of medicine and surgery. If the physician can participate in and guide these changes, all will profit more. If he does not, others will; for the public knows better all of the time just what medicine offers to human beings in the way of guidance, comfort and protection.

It seems to me that in the hospitals and medical schools we have centers which should be used by the medical profession in the development of plans for widespread care of the sick. It is inevitable that more and more subsidiary help will be needed to make it possible for the carefully trained physician to do what he is trained for. Nurses, laboratory workers, physical therapists, technical assistants, secretaries and pharmacists multiply what the physician can do for his patient and for the public. These should be organized by the doctor and not for him. There is a great field for the units of government in public health but not in

the private care of the sick. Sickness is individual, personal; and when it has no public health aspect it should remain a family and personal responsibility. Facility in making medical care available to all will come through organized procedures on the insurance principle under the guidance of the profession, or it will come as a procedure of government, cursed with the inevitable, inelastic, tradition-ridden, cautious bureaucrat. The way we use the hospitals and medical schools of today will largely determine the medical future of our people.

Points to be borne in mind with regard to the medical course.

During this period of continuous session in the medical schools, of the shortage of interns and practicing physicians and the diversion of a considerable portion of the medical profession to war service, there are a few points that I think should be borne in mind in connection with the medical course:

1. There is less diversity in the preliminary training of the medical student. For many years we have had the advantage of men trained in different fields of knowledge entering our medical schools, so that a class was made up of students with some trained in the classics, others far advanced in chemistry and bacteriology, others in the field of language and literature. All of this has made medical teaching stimulating and interesting and has provided physicians with cultural interests covering the whole domain of human activity. It is desirable that as soon as possible we resume more elaborate and longer training for at least a considerable portion of our medical students.

2. At this time military medicine, emergency surgery, the relationship of medicine to society, and physical medicine should have special emphasis.

3. The intern year and residencies have been cut by war needs. This will lead to an unusual call for hospital training of physicians returning from war service in order to prepare themselves for general practice or for the specialties. While the specialty boards can give a certain amount of credit for military service, they cannot certify men who have not had the actual training in the laboratory or in the clinic and hospital required for the practice of a specialty. We are going to lose the medical student early and get him back after some war service demanding more training. All of this means that we must keep our medical structure elastic and responsive.

4. Nurse education needs to be reviewed in the light of our present experience. It would be desirable to prolong and diversify the period of preliminary training. Many nurses will enter executive fields requiring much more than the minimum training necessary now with the cadet system.

5. The very large number of casualties of industry and of the highway will profit from the forced experiences of war, provided our medical schools promptly mold their instruction to conform with the new knowledge of wounds of the body and of the damage inflicted on the nervous system by fatigue, malnutrition and strain.

All in all, we can take great pride in the achievements of the medical schools of our nation and look forward with confidence to the further adjustment of these war years and those of peace to follow.

READJUSTMENTS OF RETURNING MEDICAL OFFICERS

WILBURT C. DAVISON, M.D.
DURHAM, N. C.

The chief worries of young medical officers are (a) postwar postgraduate training, (b) locations for practice, (c) the overcrowding of the profession by the increased number of physicians being graduated during the accelerated war program, (d) the effect of the extension of socialized medicine and (e) specialization versus general practice. We must do more postwar planning for these returning physicians than those who stayed at home in the last war did for us who were in the services.

(a) *Postgraduate Training.*—The first of these problems is being considered elsewhere on this program.¹ The ideal method would be for every medical officer to return to his own or some other medical school or hospital for six months to two years of intensive work.² Plans are being made to provide a sufficient number of postwar hospital and laboratory appointments and to furnish financial support to the returning officers and institutions.

(b) *Locations for Practice.*—The second problem is even more serious, but it also is soluble. Every medical school receives numerous requests for physicians: I have a list of two hundred and seven communities which are in need of medical service. All of these rosters might be assembled by the new Council on Medical Service and Public Relations or the Committee on Postwar Planning of the American Medical Association, and the locations thoroughly investigated. A subcommittee of the latter is already at work on the problem.³ The Procurement and Assignment Service also has accurate data on the medical needs of many communities. Most physicians hesitate to register with commercial medical employment agencies but would welcome authentic information from the American Medical Association.

This survey should be done by personal visits. Questionnaires help but do not supply all the information needed about the areas which request physicians. Accurate figures are necessary on the population in the town and surrounding country, the number of physicians in proportion to the population and the area, the economic status and per capita wealth of the community, the schools, churches, living conditions and recreational facilities. Such an investigation will be expensive, but, with all of the present interest in the relocation of physicians, funds should be available. A great service can be rendered by the collection of accurate data on communities which are in need of physicians and which can and will support a physician. This information will be very helpful to returning medical officers, not only to those who have never been in practice, but also to those who had been established in practice, for many physicians in the last war changed to new locations on their return.

From the Department of Pediatrics, Duke University School of Medicine and Duke Hospital.

3. Lee, R. I.: Personal communication to the author.

(c) *Possible Overcrowding of Profession.*—Under the Army-Navy Specialized Training Program medical schools have increased the sizes of their entering classes by 10 per cent and are admitting students every nine instead of every twelve months, thereby increasing the output of physicians by 46.6 per cent: 10 per cent (additional students) + 36.6 per cent (admission every nine months of a class 10 per cent larger). Starting in 1945 the Army and Navy will assign to the various medical schools the premedical students being selected and prepared under the ASTP and V-12(S) programs, the Army taking 55 per cent of the places and the Navy 25 per cent. The medical schools can fill the remaining 20 per cent with students ineligible for military duty—cripples and women—who can treat the civilian population, one of our great war needs. As a result many more women probably will study medicine, for the men ineligible for the Medical Corps are very few. Perhaps it is as well, for women physicians, being "expendable" through marriage and retirement after the war, probably will remove approximately 15 per cent from this 46.6 per cent increase in young physicians. However, although the present U. S. physician-population ratio is 1:719, the increased number of graduates during the next few years will not produce overcrowding of the medical profession. Any possible excess will be absorbed by the needs of the Veteran's Bureau, the large postwar standing Army and Navy, the compulsory universal training program, the medical services of the occupied territories, and last but not least the increased demand for medical care due to the education of the public.

The greatest problem of medical care in this country is its maldistribution, with a ratio of physicians to the population ranging before the war from 1:544 in New York state⁴ to 1:5,164 in one North Carolina county.⁵ A better means of distribution of physicians is one of our greatest needs.

It is frequently forgotten that the people in some of the areas in which physicians are scarce do not have the means or desire to seek medical service. For example, Georgia has only half as many physicians in proportion to the population as Washington, D. C., yet the average physician in Washington sees as many patients per week as his Georgia colleague.⁶ In other words, the demand for medical service in Washington is twice as great as in Georgia; as a result, Washington can and does support twice as many physicians in proportion to the population as does Georgia.

A survey of three rural counties in Tennessee, Georgia and Mississippi in 1931 demonstrated that the money spent for medical care was inadequate to remunerate practitioners or to support hospitals and other medical facilities.⁷ There is a correlation between the economic situation in a state and the number of physicians therein: "Physicians behave, in the conduct of life, about as any group of sensible people would be expected to. They do business where business is good and avoid places where it is bad."⁸

Just before the war, owing to the improvement in farming conditions but more especially to the dearth

of physicians and to the absence of competition, the incomes of the keener rural doctors often were equal to those of their urban brethren and even better, if the cost of living is considered. In some areas, subsidy by the community has been attempted, although this policy generally has been unsatisfactory.⁹ In recent years the number of rural physicians in North and South Carolina increased 8 per cent without subsidies. However, county, state or federal subsidies or other organized financial aid to some of these areas may be necessary to attract returning medical officers to settle there, and plans should be started now so that the funds will be available when the war is won.

On the other hand, the economic status of the community is not the only factor in the maldistribution of medical care; the interest of the population in its own health is of even greater importance. For example, in Durham, N. C., in spite of the adequacy of physicians, hospitals, baby clinics and health department, fifty-six of the one hundred counties in North Carolina in 1941 had a lower infant mortality rate than Durham, and thirty-eight of the forty-eight states in the country had a lower infant death rate than North Carolina.¹⁰ The parents either are ignorant of the medical resources available or are too careless or uninterested to use them. Fortunately the old adage "You can lead a horse to water but you can't make him drink" is no longer true. If, through advertising, a public demand can be created for automobiles, electric ice boxes, certain brands of cigarets and "patent" and home medicines (which represent 14 per cent of the present medical costs)¹¹ the people can be taught to seek adequate medical service. Better medical care can be obtained for a smaller amount of money spent in teaching the public to utilize medical facilities than would be required for subsidizing physicians to go to the areas in which they are needed.¹² The law of supply and demand is still in operation. The public gets the product it demands, whether it is medical care or a nationally advertised variety of tooth paste. However, the demand in many of these communities must be created. The American Medical Association, American Academy of Pediatrics and county, state and federal health services might employ publicity experts to conduct national, state, county and city advertising campaigns in newspapers, busses, billboards and radio and through churches, schools, the Parent-Teachers' Association, the American Legion and other organizations on the necessity for medical care.

The availability of hospitals is another weighty factor in attracting recent graduates to practice.¹³ The young, highly trained physician of today does not feel that he can practice modern medicine without access to a hospital. Even though 90 per cent of patients can be and are properly cared for in their homes or in the physician's office¹⁴ the laboratory facilities of a hospital are essential for the diagnosis of many conditions. In addition, local hospitals influence the older physicians who have kept abreast of the times to remain in rural

communities. The establishment of rural hospitals in North and South Carolina with the aid of the Duke Endowment is improving the medical service in the country and is attracting young physicians there. The influence of the location of hospitals on the distribution of physicians is strikingly illustrated in North Carolina; in the fifty-seven counties which have hospitals there is 1 physician to every 1,149 people, and in the forty-three counties without hospitals the ratio is 1:2,034.¹⁵ Of the 638 recent graduates who have settled in North Carolina since 1925, only 64 located in towns without hospitals.¹⁶ One of the major objectives of the Duke Endowment is to bring about a better distribution of well trained physicians by an improvement and an extension of available facilities for the practice of modern medicine which exist in and not apart from hospitals.¹⁷ A similar plan for the United States as a whole is being established by the United States Public Health Service and the Federal Works Administration.

In rural areas in which the towns are too small to support an individual hospital or too scattered to maintain a combined hospital a "medical station" with a nurse and a technician and affiliated with a medical center would increase the physician's effectiveness and improve rural medical service.¹⁸

Not only do rural communities need hospitals and laboratory facilities but equally important, if they have a hospital, they require financial assistance to enable the people to use the hospital. Bed occupancy is as vital as the beds themselves. Modern medical service cannot exist without hospitals, and hospitals cannot exist without support from endowments, state, county or federal aid, or voluntary hospital care associations. Because of present financial conditions, endowments are becoming rare, and state, county and federal aid may bring political control.¹⁹ The voluntary group hospital association seems to be the logical answer.

(d) *The Extension of Socialized Medicine.*—This is not the only solution of the problem of the maldistribution of medical care and its costs.²⁰ The medical profession today is conducting more social experiments in the methods of distributing medical services than all the proponents for change have ever conducted. Out of the two hundred and fifty or more projects that are being studied or operated by county or state medical societies it is hoped that methods may be found to supplement existing medical facilities wherever necessity demands.

The American Medical Association is not opposing the low income groups in this country in their effort to secure good medical service at a cost which they can reasonably meet. It has endeavored to discover more suitable methods to assist these people to solve their medical problems. It does oppose the exploitation of the poor, and it is unalterably opposed to any scheme that would give the poor an inferior quality of medical care.²¹

Medical care must be provided for the indigent and their dependents. At present it is available in most areas but is sometimes difficult to find, its quality is often poor and the payment for it usually is absent. Every one agrees that the poorest third of the population needs the most medical care and gets the least. The county medical societies, health departments and public welfare agencies are increasing their efforts to solve this problem. The following methods for providing medical care to the indigent from local, state or federal funds should be considered: 1. The employment of county and city physicians is the cheapest method for the taxpayer, but the medical service often is mediocre. However, it may be the only practical solution in sparsely settled areas. The payment of larger salaries and the possibility of advancement would attract better physicians. 2. Medical service to the indigent on a fee-per-call basis under the control of the county medical societies, similar to the former FERA plan²² or the present Farm Security Administration program,²³ has proved satisfactory to the patient and the physician, though it is more costly than the employment of a county physician. 3. Payment to group clinics and hospitals and traveling expenses for the 15 per cent of indigent patients who need specialist, diagnostic, surgical and hospital care are essential. Many counties and states are recognizing this responsibility. 4. Group clinics and hospitals should be provided and supported in areas which need them. 5. Medical care should be separated from unemployment insurance and cash sick benefits.

To proceed rashly without going through progressive stages will produce worse medical service than exists under the present system. Ill considered and hasty legislation is as likely to be as harmful as beneficial. Whether a generation will be necessary for the transition or a century, as in public education, only sound experiment and experience can tell.

(e) *Specialization versus General Practice.*—General practitioner care is the greatest need, as 85 per cent of illness can be handled successfully by family physicians. Only 15 per cent of the patients need specialist, diagnostic, surgical and hospital care. Economic factors and the specialty boards may decrease the present plethora of specialists. Before Pearl Harbor, 60 per cent of the graduates of Duke University²⁴ and up to 75 per cent in other medical schools²⁵ became specialists, but under the present 9-9-9 internship-residency quota plan only 17 per cent of the graduates will be able to obtain a maximum of twenty-seven months of hospital training and even this amount will not produce a specialist. The majority of recent graduates will have had only nine to eighteen months of hospital experience, most of it as rotating interns. When these medical officers return, few will be able to afford the time and money to qualify for the specialty boards and will be forced into general practice. However, on their return from the war they will need six months to two years of hospital or laboratory work to reequip themselves, for a general practitioner needs a sound scientific background as much as if not more than a specialist, so that

he may be capable under all circumstances of advising the family whether the patient needs to consult a specialist.²⁶ Fortunately the opportunities for preparation for general practice are more abundant than are the residencies required by the specialty boards. If a graduate plans to enter general practice—a consummation much to be desired—a straight medical internship for one year, a straight pediatric internship for six months and a straight obstetric internship for six months would equip him much better than the usual rotating service.²⁷

One difficulty in persuading young graduates to go into general practice is their erroneous feeling that it does not carry the same dignity as that of a specialty. Since the specialty boards were created, the students have increasingly obtained the impression that general practice is what the specialists discarded. As a matter of fact, general practice is just as much a specialty as pediatrics, and the present misunderstanding would be corrected if general practice had its own specialty board and requirements.

Furthermore, the specialties are overcrowded.²⁸ For example, there are 4,205 pediatricians, of whom 2,205 give their full time to the specialty;²⁸ 2,162 of them have been certified by the American Board of Pediatrics.²⁹ It is possible that the opportunity for successful pediatric private practice may be impaired because of a supply greater than the demand. It is doubtful whether the public can support a larger number of pediatricians, as half of the babies born each year are in families on relief or with an annual income of less than \$1,000. Fair remuneration to the physician is essential to good care.²⁸ As the average age of practicing pediatricians is approximately 40 years and as replacements will be slow, graduates of today who wish to care for children may have difficulty as specialists and probably should enter general practice or obtain health department positions, even though this statement may be interpreted as a lamentation of Jeremiah or a tribulation of Job.³⁰

The fact that 60 to 75 per cent of the prewar graduates are, or plan to be, specialists, who are needed by 15 per cent of the patients, is an indication not only of the overcrowding of the specialties but also of the urgent need and wide open opportunities for good general practitioners. This plethora of specialists has caused such competition and crowding that in many communities the financial rewards of general practitioners, with their reduced competition, are higher than those of specialists. The modern medical curriculum often is blamed for this trend toward specialization, but the tide toward general practice is turning without any changes in the medical schools; it is a response to economic conditions.³¹ However, the number going into rural practice is still falling²⁵ except in North and South Carolina.³² In these two states, as previously mentioned, the establishment of rural hospitals through the aid of the Duke Endowment is improving medical service in the country and attracting young physicians there.

CONCLUSIONS

1. Hospitals and laboratories, especially those attached to medical schools, should increase their appointments to provide postwar postgraduate training for the returning medical officers.

2. Authentic information on locations for practice, possible overcrowding of the profession and socialized medicine should be collected by the American Medical Association, so that it can be furnished to the returning medical officers.

3. The majority of the recent graduates who are in the armed forces probably will go into general practice.

PROBLEMS OF POSTWAR MEDICAL EDUCATION

HAROLD S. DIEHL, M.D.

MINNEAPOLIS

In the decade before the war, medical education in this country reached a standard of excellence hardly dreamed of a generation ago. Teaching staffs were stronger and facilities more adequate than ever before. Entrance requirements were raised, curriculums revised and expanded. Students admitted to medical schools were carefully selected from large numbers of potentially qualified applicants. The result of all this, presumably at least, has been that our medical graduates as a group are better qualified than ever before to undertake the practice of medicine.

With the war, changes in medical education were inevitable. Premedical requirements have been reduced from three or four years to two years of college work. The medical course proper has been accelerated by the elimination of summer vacations, thereby concentrating the work of four academic years into three calendar years. The number of students accepted for admission to medical schools has been increased by approximately 10 per cent. New courses in first aid, tropical medicine and war medicine have been introduced into the curriculum, and special emphasis in regular courses has been given to such medical problems of the war as shock, hemorrhage, fractures, communicable disease control, sanitation and aviation medicine.

In postwar America the status of medical education will depend primarily on the conditions existing in our country at that time. If we should lose the war or if our enemies are able to force a stalemate, we can anticipate either complete regimentation or continuation of our country as a vast armed camp. In either case the pattern of medical education will be determined not by medical educators or by the medical profession but by government itself.

Assuming, on the other hand, that we shall be victorious, the termination of the war will require decisions as to whether these changes in medical and premedical education shall be continued. Most of them were considered undesirable when introduced and were accepted with reluctance by medical educators. Hence there is certain to be much sentiment to return immediately and completely to the prewar program of medical education. This program was developed on the basis of long experience and critical evaluation and was considered reasonably sound and adequate. Certainly such a pro-

Read before the Fortieth Annual Congress on Medical Education and Licensure, Chicago, Feb. 14, 1944.

Published in part in the *Annals of the American Academy of Political and Social Science* 231: 88 (Jan.) 1944.

gram should be accepted as at least the framework of the medical education of the future.

Yet to return blindly to a pattern of the past is to close our eyes to the possibility of improvement by breaking with tradition. Wartime experience with the accelerated curriculum and reduced entrance requirements should be carefully evaluated and considered in postwar planning. It is quite possible that some of the changes in medical education which have been made as adjustments to wartime conditions may have merit also for peacetime. There has, for example, long been concern over the increasing age of graduates from medical schools. With three or four years of college work preparatory to the study of medicine, four years in medical school and one to two years of internship, most physicians are between 27 and 28 years of age before they are ready to begin independent professional work. Add to this several years to establish a practice or three to five years of graduate training and such physicians are 30 years old before they are in a position to establish a home or to start the practice of a specialty. Perhaps the pendulum has swung too far in the direction of the prolongation of undergraduate medical training.

Population per Physician in Various Countries

United States.....	1 physician to 750 people
France.....	1 physician to 880 people
Netherlands.....	1 physician to 1,250 people
Denmark.....	1 physician to 1,400 people
England and Wales.....	1 physician to 1,490 people
Germany.....	1 physician to 1,500 people
France.....	1 physician to 1,600 people
Norway.....	1 physician to 1,760 people
The Netherlands.....	1 physician to 1,820 people
Belgium.....	1 physician to 1,850 people
Sweden.....	1 physician to 2,800 people

Medical education has never been static. Hence it is probable that the postwar period will bring forth certain modifications in the program based on wartime experience. These modifications are likely to be in the direction of more attention to the adjustment of teaching loads to available staff and facilities; continuation of a certain amount of acceleration; further trends from didactic to laboratory and clinical teaching, and more emphasis on preventive medicine in its broadest aspects such as nutrition, healthful living, geriatrics and industrial hygiene, as well as the prevention and control of communicable diseases.

SIZE OF MEDICAL CLASSES

In the early years of medical education in this country the number of students was limited only by the number of applicants and by their ability to pay the required fees. At one time 162 medical schools existed, and more were organized whenever there were prospects of additional students. Establishment of standards of accrediting for medical schools and the reduction of their number to 66 medical schools and 10 schools of basic medical sciences caused a great reduction in the number of graduates.

At one time prior to the accrediting of medical schools the annual number of graduates reached 5,747. This was in 1904, when the total population of the country was approximately 84,000,000. With the elimination of substandard schools a rapid decline in the number of medical graduates occurred, reaching a low of 2,520 in 1922. Subsequent to that date the number of graduates gradually increased to approximately 5,200 a year

in the several years before the war. This is almost 50 per cent more than the number of physicians who die each year and represents an annual net increase of 1,600 to 1,800 physicians for the country as a whole, a rate of increase among physicians in excess of that among the general population. Furthermore, at the beginning of the war the United States had the highest ratio of physicians to population of any country in the world. The accompanying table¹ shows the prewar population per physician in countries with the better developed medical facilities.

The accelerated medical course and the increase in the size of classes will produce about 7,500 graduates annually. This is approximately double the number of deaths among physicians in recent years. The war will doubtless cause an increase in the death rate among physicians, but even allowing for this the accelerated program of medical education should provide a sufficient number of physicians to meet the needs of both the armed forces and the civilian population at the close of the war. Whether the number of medical students in training should then be immediately reduced is dependent on several factors at present unpredictable. Among these are (1) the number of physicians who will be killed or disabled during the war, (2) the number who will be retained in the armed forces or other governmental agencies for domestic and foreign service and (3) the postwar need, demand, facilities and organization for the provision of medical services to the civilian population.

It is clear however that, in the interest both of sound medical education and of good medical care, medical schools should appraise their situations and reduce the size of their student bodies to the number that can be properly trained with available staff and facilities. Unfortunately, some of the large increases in the number of students accepted for training during the war have been in medical schools with relatively meager facilities. Such situations should be corrected without delay.

SELECTION OF MEDICAL STUDENTS

In recent years the number of applicants for admission to medical schools has been more than twice the number of students accepted. This has made selection possible and doubtless has resulted in a higher average level of ability among medical students than existed prior to such selection. Even so, most medical schools accept the last 20 to 25 per cent of students with distinct reservations as to their qualifications, intellectual or personal, for the study or practice of medicine. If possible, this lowest fourth should be replaced by students of greater promise.

There is some opinion that the cost of medical education prevents many able students from undertaking it. This may be true. Yet the large proportion of medical students who are wholly or partially self supporting indicates that, at least for many with sufficient ability and determination to secure a medical education, the financial difficulties are not insurmountable. On the other hand, the lack of funds doubtless deters some from undertaking the study of medicine and handicaps others in securing a medical education.

Under the Army and Navy College Training Programs economic considerations are completely removed, both as factors in determining who shall study medicine and as handicaps in medical school to students with limited resources. This represents an important edu-

1. Figures for countries other than the United States from Final Report of the Commission on Medical Education, New York, office of the Director of Study, 1932, p. 99.

cational experiment the results of which should be carefully evaluated. If it appears that as a result of this subsidy appreciable numbers of superior students are enabled to undertake the study of medicine, and if these and other students with limited financial resources receive better medical educations because they are able to devote their time and energies undividedly to their studies, then it would seem in the public interest that more adequate loan or scholarship funds should be made available to aid medical students in the post-war era.

PREMEDICAL EDUCATION

For a number of years before the war practically all medical schools required three or four years of premedical college training as a prerequisite for admission, and 98 per cent of the students admitted to medical schools in 1941 had completed three or more years of college work. The purpose of premedical requirements is to provide medical students with a sound foundation in the sciences on which medicine is based, a familiarity with the social sciences concerned with human relationships, an ability to use the English and at least one foreign language and an acquaintance with other fields which contribute to a liberal education.

In 1825, in answer to objections to establishing the medical school of the University of Virginia at Charlottesville instead of at Richmond, where facilities for clinical instruction were more adequate, Thomas Jefferson indicated that the chief aim of this medical school "at first, was not to give a professional education but simply instruction in a branch of liberal culture which every accomplished gentleman was presumed to have studied."² Most medical educators do not go as far as Thomas Jefferson in this regard but they are anxious that physicians should have a reasonably good general education, meaning thereby "those nonspecialized and nonvocational phases of education that should be the common possession of educated people in a democratic society."³

The reduction of the premedical course to two years of college work has necessitated the elimination of some desirable science courses and most of the opportunities to become acquainted with other fields of knowledge. These opportunities should be restored at the earliest possible moment.

However, consideration of the several groups of students who will be desirous of preparing for the study of medicine immediately after the war would seem to make gradual return to a longer premedical course desirable. Students from high school could well be required to meet normal peacetime requirements. On the other hand, students who have served for some time in the armed forces will be older, anxious to begin their professional studies and impatient of prolonged premedical preparation. For them the curtailed wartime requirements might well be considered acceptable. Students who at the close of the war will have partially completed their premedical requirements under the Army or Navy College Training Programs will constitute an intermediate group.

ACCELERATION

Under the shorter premedical program students start the study of medicine a year or two younger than would otherwise be possible. Many feel that such

students will be lacking in the intellectual maturity, the educational background and the sound judgment so important for the study of medicine. Yet the adding of one or possibly even two or three years to the professional life of most physicians is no small consideration. Thirty-five years ago President Lowell of Harvard wrote "With the long period of special training now required in every profession, there is a universal cry that men are beginning their careers in life too old, and that the period of education is too long. Disease and death are not postponed because a man starts upon the practice of his profession a year or two later than is necessary. His period of active life, his achievements and his usefulness are simply curtailed to that extent."⁴ Over the years discussion of this problem has continued; but instead of a reduction there has been an increase in the age of graduation from medical school.

The possibility of saving time in premedical college preparation has been mentioned. The wisdom of much reduction here seems dubious; but there are definite possibilities of saving valuable years in the elementary and secondary schools. For superior students the lock-step of most elementary and secondary education is not only unnecessary but actually deleterious to initiative and serious scholarship. Furthermore, much of the work of the last two years of high school is repeated during the first year in college. It would seem, therefore, that for many students at least one or two years could be saved by acceleration in the elementary and secondary schools and by telescoping the last year of high school with the first year of college.

The question of immaturity on the part of such accelerated students doubtless has some validity. There is, however, no evidence that the learning capacity of a person is greater from 21 to 25 years of age than it is from 18 to 22, and there is abundant evidence that young people of ability mature rapidly under responsibility and challenging purposeful work.⁵ Sound judgment in medical matters is developed by clinical experience in the wards of hospitals or in medical practice, not by spending unnecessary years in elementary and secondary schools.

The accelerated medical curriculum, with the elimination of summer vacations and the acceptance of new classes at nine month intervals, was adopted for the duration of the war in order to graduate physicians earlier and in larger numbers for service in the armed forces. These demands will taper off with the cessation of hostilities. Therefore, unless there are needs for large numbers of physicians which cannot now be foreseen, most medical schools probably should and will return promptly to the annual admission of new classes. This is necessary if the faculties of medicine are to have time for the scientific and scholarly work which is the foundation of modern medical education.

With an annual admission of students and a reduction in enrolment to prewar levels, the annual number of medical graduates will be reduced and stabilized whether or not the acceleration of the medical course proper is continued.

The chief argument in favor of the continuation of the accelerated program in the medical school is that it permits students to graduate a year earlier than would otherwise be possible, thereby making available to them an extra year for graduate study or for the practice of their profession.

4. Lowell, L.: *At War with Academic Tradition in America*, Cambridge, Mass., Harvard University Press, 1924, p. 257.

5. Pressey, S. L.: *Acceleration and the College Student*, *Ann. Am. Acad. Polit. & Social Sc.* 231: 54 (Jan.) 1944.

Against continued acceleration the major arguments are that many students need the summer vacations to earn money toward the expenses of the ensuing year, that some students pursue additional studies during the summer months which contribute materially to their medical education and that the students and faculty need vacations during the summer months.

Probably the first is the most valid of these arguments. Many students utilize the summer months to earn money for their next year's tuition. Yet the amount of money which the average student earns during three summer vacations, approximately \$600 at the University of Minnesota, is small compensation for a year out of his professional life. If adequate loan funds or scholarships could be made available to students who need them it would be preferable, even from an economic point of view, if medical students were able to accelerate their courses of study and graduate in the shortest possible time. Of greater significance is the additional year of service which graduates under the accelerated program can render to society.

The work that some students engage in during summer vacations undoubtedly contributes to their medical education, but the proportion of students who profit professionally by the work done during vacations is too small to provide a strong argument for continuation of the long summer holidays.

The argument that students and faculty members need vacations of three or four months during the summer is open to question. Even under the accelerated curriculum students have four to six weeks of vacation annually, and if classes are admitted only once a year the faculty will have little more teaching under the accelerated program than under the normal curriculum.

THE SUPPORT OF MEDICAL EDUCATION

Financial limitations make it practically impossible for certain medical schools to conduct a truly first class program of medical education. Some of these schools have attempted to increase their budgets by admitting excessive numbers of students. This is truly "selling the birthright" of medical education "for a mess of pottage."

The late President Lotus D. Coffman of the University of Minnesota said that "there are certain things in life for which we pay whether we get them or not." He was referring to general education, but his statement is even more applicable to medical education. If medical education is not adequately supported, the public will receive inferior medical care and will pay for this in terms of unnecessary illnesses and even of life itself.

This public must be made to realize that one of the fundamental requirements for a sound program of medical education is adequate financial support and that less than this is not economy but tragic shortsightedness.

FACULTY RECRUITMENT

The most serious difficulty which medical schools are experiencing in maintaining satisfactory standards of medical instruction during the war is the depletion of their teaching staffs. Every medical school has lost a considerable proportion of its younger faculty members—the group which in most schools carries a large part of the undergraduate teaching. It is from this group also that promotions are made into senior teaching and research positions. Some of these men will return to their former positions after the war; others will be lost at least to medicine forever.

Of equal or possibly even greater concern is the disappearance of the several hundred graduates in each medical class who in normal times would be preparing themselves for careers in medical teaching and research. Multiply this number by the duration of the war and the seriousness of this deficiency is obvious. One of the great foundations has recognized the importance of this "lost generation" to the future of medical science and is planning to aid in the postwar training of a few selected men from this group. This is a splendid example and beginning, but it is essential also that medical schools keep in touch with young men of ability who are interested in academic careers, arrange for their prompt return at the close of the war and then plan to expedite the completion of their training. To fail to do this may well prove to be the most serious permanent loss suffered by medical education from the war.

THE INSTRUCTIONAL PROGRAM

Few changes in the medical curriculum or in instructional methods have been made in connection with the accelerated program. In this medical schools have followed the line of least resistance—a line which is likely to be followed also in making postwar readjustments to a peacetime basis. On the other hand, periods of stress frequently offer opportunities to make changes or adjustments which are difficult in normal times.

In most medical schools the curriculum has become overcrowded and rigid. Yet new developments and even some new fields, such as physical medicine and social medicine, must be included in the instructional program if our graduates are to be prepared to deal with the medical problems of the future. In one of the large clinics of this country 10 per cent of all patients are referred to the division of physical medicine, a field in which few medical schools provide any instruction worthy of the name.

Social medicine has two connotations. One is sometimes called the "social component" of medicine: that is, the social, environmental and economic factors related to the patient's illness or recovery. Increasing attention is being given in medical schools to this field. The other connotation concerns the relationship of the physician and the medical profession to the society which it serves. It is apparent that this society is becoming increasingly interested in the distribution of medical services. To direct this interest to the benefit of all concerned, it is essential that the medical profession understand the issues, the proposals and the plans and exhibit constructive leadership in this field.

These and other subjects we would like to present to our medical students but, unfortunately, there is no time for them in the curriculum. Each professor so thoroughly appreciates the importance of his own subject that he feels that he should have more time, not less, in which to present it.

If the medical curriculum is to be kept in balance with developments in medical science and medical practice, reappraisal of both the curriculum and instructional methods must be made from time to time. Possibly the time given to some subjects should be curtailed and that given to others extended. The postwar period offers a rare opportunity to make such reappraisals and readjustments. May the medical schools have the vision, the courage and the wisdom to take advantage of these opportunities.

DISTRIBUTION OF MEDICAL CARE

A POSTGRADUATE PROGRAM TO FIT A PATTERN
OF MEDICAL PRACTICE

SAMUEL PROGER, M.D.

BOSTON

Medical schools have come more and more to accept the responsibility for the continued education of their graduates through postgraduate programs. Such postgraduate programs have been generally helpful. They can, however, be considerably more helpful; they can, in fact, serve as a major factor in the solution of the great problems involved in the distribution of good medical care, problems which are at present under urgent discussion.

Essentially the total medical problem consists of (1) the maintenance of high standards of undergraduate medical education, (2) the satisfactory distribution of medical care and (3) the purchasability of this medical care by the public. The problem of the maintenance of high standards of undergraduate medical education in this country is being attacked in an impressive manner by the medical schools. The second problem, that of distribution, is a complex one. It involves (a) the continued education of the practicing physician, (b) the establishment of channels for the quick dissemination of new advances in medical care, both of a technical and of a clinical nature, and (c) the creation of physical facilities for the management of the sick or potentially sick patient. Only this last phase of the problem of distribution, namely the creation of physical facilities, is basically economic.

There remains the final phase of the problem, that of making purchasable good medical care. The problem of the purchasability of medical care is purely economic and must in some way sooner or later be met to the extent that every person can obtain at least the minimum essential medical care. This is not the place for a discussion of the merits of the various methods of financing medical care in this country. If one proceeds on the assumption that some method of financing has been established, that the economic problem has been solved, we are faced then with the problems of the quality of medical care and its distribution. Quality and distribution are placed together because it has been demonstrated that they are interrelated and can be satisfactorily encompassed in a broad postgraduate educational program such as has been set up at the Tufts Medical School through the Bingham Associates Fund. This program is, briefly, a plan to extend medical benefits to small communities through a series of postgraduate activities. The New England Medical Center, and more particularly the Joseph H. Pratt Diagnostic Hospital, serves with the Tufts Medical School as the central base for the development of the program, which is a coordinated effort toward making better medical care available to more people of New England. The program functions through the medical school and affiliated hospitals of various sizes and in widely scattered communities. There are small community hospitals in twenty-four towns in Maine, larger hospitals in regional centers in Lewiston and Bangor and the medical school and hospital center in Boston. The work is divided into three main divisions: (1) clinical diagnostic aid, (2) postgraduate medical courses and (3) hospital extension services. In offering clinical diag-

nostic aid the base hospital serves as a complement to and not as a substitute for the affiliated hospitals. It becomes a clearing house for such problems as the affiliated hospitals may wish to refer. The organization for clinical affiliations is discussed later. The postgraduate medical courses aim to improve the capabilities of the physicians who supply medical care in the various communities. These postgraduate courses are of the extramural as well as of the intramural type. The hospital extension services are designed to improve the hospital facilities in small communities. These small community hospitals are affiliated with larger hospitals in the regional centers. The regional centers are in turn directly affiliated with the medical school center in Boston. It is intended that the small communities maintain full opportunities for independent work but that this work be integrated with that of the metropolitan and regional centers in such a manner that there may be established regular and directed channels for the quick dissemination of medical developments from the large medical centers to the smaller communities. In these hospital extension services are included pathology, laboratory aid, electrocardiography, radiology, dietetics and library assistance.

If the health of the citizens is properly the concern of the government, the government's first duty should be to make possible the purchasability of what is at present offered in medical care. Such a program as is here outlined might contribute to the solving of many of the remaining problems of good medical care and its distribution. As a matter of fact it is possible that, with the creation of sufficient purchasing power through a satisfactory economic program, the problems of distribution and availability would more or less solve themselves through the stimulating influence of this purchasing power. The successful development of "prepaid medical clinics" has demonstrated essentially that point, namely that, as money circulates freely, facilities are created. When one considers the tremendous forward strides which American medicine has taken, particularly in scientific and educational achievements, despite inadequate and uneven financial support, it is not too much to anticipate that when there is an adequate and even source of income the problems associated with the distribution of these scientific advances will also be successfully met. It is these scientific advances of medicine which have created the problem of distribution. A hundred years ago the medical care obtainable by the rich and fortunately located was not much better than that available to the poor and isolated, largely because there was at that time but little difference between what was considered good medical care and no medical care. As medicine advanced this difference became increasingly great, so that there arose the problem with which we are now faced: namely, that of bringing the improved medical care to more and more people through an economic program which makes this care purchasable and through a program of distribution which makes it available.

It may be argued that only an insurance program of national scope and under government control can make it possible for the lay public to afford and hence demand the best medical care. There is no justification, however, for assuming that the noneconomic aspects of the whole problem require government supervision. There is no reason to believe that voluntary medical centers cannot satisfactorily manage these aspects. You can legislate an insurance program which will make it possible for every one to purchase medical care. You

can even legislate professional and hospital standards. But you cannot legislate the discovery of insulin or a method for estimating the level of phosphatase in the blood or countless other advances. Such advances are stimulated by certain influences which have operated in a free scientific atmosphere and which may or may not operate in a rigidly controlled government atmosphere. The medical school has been largely responsible for the advances and the present high standards of medicine in this country. The medical school, in addition to creating standards and stimulating scientific advances, may also see to it that such advances are continually distributed to the people for whom they are ultimately intended. A more extensive postgraduate program can achieve such a goal. For this purpose the medical school must have full clinical facilities. Where medical schools are not available, teaching hospitals should be utilized.

Essentially the problem of supplying clinical facilities to a given region, as we view it, involves the setting up of a number of hospitals over wide areas whose total function will be that of a single coordinated and balanced institution. It is the horizontal instead of the vertical development of hospitals. It is decentralization with coordination rather than centralization with subordination.

As to the medical center hospital itself, it should serve as a source of specialized aid which would not otherwise be satisfactorily available to the affiliated communities. It should not be concerned with simply providing another building with more beds for patients with pneumonia or heart failure, or for those who require appendectomies, herniotomies and so forth. In other words, it should not be simply another hospital. The mass of work should be done locally by community hospitals, more advanced work should be done in regional centers, and only the final filtered cases should be handled in the medical center. The present tendency of centralizing more and more work in larger and larger institutions will ultimately become uneconomical from the medical point of view and certainly undesirable from the patient's point of view, particularly when the patient must come from a distant community. A scattered group of hospitals, working independently but in a coordinated manner, could be far more effective in handling, let us say, 3 to 4 thousand patients spread throughout small communities in New England than one hospital in Boston ever could. The purpose of the New England Medical Center is not to care for a cross section of medical population but to set up a cross section of hospitals to care for this population. The alternative of one large, ever expanding central hospital to look after everybody would create a situation comparable to that in which all legal problems, for example, might have direct access to the Supreme Court. Just as it is desirable to have a series of progressive courts, all of equally high standards, to handle progressively complex legal problems, so it is desirable to have a series of progressive hospital units to care for increasingly complex medical problems.

The medical center should develop on the principle of continually decentralizing certain functions to units which are being made increasingly adequate; and it should allocate to itself only those functions which it alone can best handle. It would be expected that new operations, new techniques and other new developments would gradually be handed down and established in the smaller units as these advances became widely acceptable. The purpose of the central unit is not to serve

primarily as a point to which patients can be referred for help. The purpose is continually to improve the facilities in the various affiliated communities to such an extent that fewer and fewer problems will need to be referred. As long as there is continuing medical progress there will be opportunity for the central unit to pass on such progress through the organization.

There is no intention to minimize the importance of large general hospitals. In metropolitan areas such hospitals are necessary if for no other reason than to care for the large local medical population. The type of organization of hospitals which I am describing is intended rather to supplement existing hospital activities in metropolitan areas for the purpose of creating better opportunities for smaller communities to keep up with the progress of medicine. This is essentially a new function for a metropolitan or teaching hospital.

One can conceive of a situation ultimately in which the various hospitals through to the smallest communities will be so intimately connected with the medical school center through a comprehensive postgraduate program that there will be very little difference between the quality of work done in the smallest unit and that in the center. When this time comes undergraduate students will be doing their clinical work in communities all along the line, graduate students will be taking their hospital internships in all the communities concerned, postgraduate instruction will be disseminated throughout, hospital extension services will make uniform the quality of the ancillary medical services (pathology, nursing, laboratory, x-ray and so on) and clinical units will be coordinated in such a way as to serve essentially as a large single clinical organization scattered over widely separated areas.

An institutional organization such as is pictured in the Tufts program points up the problem of professional organization for medical care. The program may seem among other things to be encouraging group or institutional practice on a larger and more widespread scale.

To the general practitioner the unusual will always remain unusual; to the specialist in an institution it can become usual. For example, 3 patients arrive from small communities with easily diagnosable undulant fever, multiple sclerosis and myxedema respectively. To the referring family doctors these are rare conditions. To specialists in an institution they may be relatively common.

Is the general practitioner, then, to be relegated to managing minor ailments and serving as a way station for the referring of all other illnesses? Not at all. The patients in most cases need be referred to institutions only for consultation and recommendations. Practically all nonsurgical illnesses, from the therapeutic point of view, can be divided into three classes: (1) the self limited, (2) the fairly easily manageable and (3) the incurable. Once the diagnosis has been established, most of these illnesses can be handled by the general practitioner as well as by the trained specialist in the best equipped medical center. The only cases which the general practitioner cannot handle are those which require certain difficult therapeutic procedures which only a group of specialists can provide. Included, of course, are special surgical procedures which will always have to be performed in some center if they are to be done well.

The general practitioner is then in a position to take care of his practice entirely satisfactorily if he can obtain a consultation and recommendations from some

central institution and if he is enabled to refer to such an institution those few patients requiring special surgical or, more rarely, special medical treatment which cannot be provided locally. In fact, if a general practitioner or family doctor can become actively affiliated with a group of hospitals such as a medical school post-graduate program like the Tufts program could provide, he may function with complete satisfaction to his patient.

A pattern for future practice then begins to emerge. It will not be a struggle between the specialists practicing in a group and the general practitioner practicing as an individual for control of medical practice with the prospect that ultimately one or the other will disappear. Rather it will be the better coordination of the best features of the two. This is the ideal for which to strive. The health of our people will be worse if it is left entirely to specialists, just as it has not been sufficiently good because in the past it was left almost entirely in the hands of the general practitioner. The two groups can be strengthened and each made more effective by the proper combination of their separate talents.

It is axiomatic that new movements tend to go to extremes. Specialization because of obvious advantages is likely to be looked on as the answer to the problems of medical care. Some attempts at such an answer have been made by the concentration of specialists in groups, as in the Mayo Clinic and the Lahey Clinic, for example. The success of such clinics only emphasizes that there is necessity for specialized aid. This success must not be taken to mean that we have discovered the answer to medical care. It would be as reasonable to assume that because of the great advantages of air and motor transportation walking will no longer be necessary. The basis of all transport will still be old fashioned walking. It is a great help, however, to be able to employ speedy transportation when necessary. The combination of the power to walk plus the power to fly, each in its place, is clearly more satisfactory than either power alone.

Here is one of the fundamental differences between the type of development for which the Joseph H. Pratt Diagnostic Hospital is striving and that of other present day clinics. The Pratt aims to complement the family doctor, whereas other clinics tend to supplant him. Something as impersonal as a clinic will never be able satisfactorily to look after an individual patient as a human being. Those who have had some experience with medical induction boards recognize them as fine examples of highly organized mass study; the assembly line applied to the medical field. For a certain type of medical work this sort of superefficiency is unsurpassed. However, for coordinating the problems of an individual patient and looking after that patient such a system is inadequate. So much time is required for the proper complete care of an individual patient that one institution cannot possibly have on its staff enough physicians to handle satisfactorily all the patients; hence it becomes extremely advantageous to farm patients out, as it were, to what might be called men in the field, or the general practitioners. In the war on illness it is largely they who in the final analysis do the actual fighting after receiving proper instruction.

On an "assembly line" the trained physician can decide in ten seconds that a patient has rheumatic heart disease with mitral stenosis. Some one must spend many hours over the succeeding years explaining the significance of this diagnosis and arranging a program of life as well as supervising general health measures.

The diagnosis can be made in an institution; the subsequent care should be handled by a family doctor.

The sick patient should first consult his family doctor. This doctor should be sufficiently well informed to decide whether he needs technical or clinical help. The facilities for such help must be made available to the family doctor, to whom the patient should ultimately return for continued care. In most instances the general practitioner can handle the patient's complaint without much ado. The general practitioner and not the patient should decide when the expensive facilities of clinics and hospitals should be utilized. If the patient has either private or insurance funds so that the general practitioner need not hesitate to ask for whatever technical or clinical help is necessary, then the situation becomes even more satisfactory.

The argument is not group medicine versus the family doctor but rather group medicine plus the family doctor versus group medicine or the family doctor. It would be difficult to prove that the ailing patient who has a well informed family doctor with ready access to the benefits of medical advances is not in the long run better off than the patient who is tagged through an impressive institution and then of necessity left more or less to his own devices.

The majority of all illnesses are easily diagnosed by the well informed and well trained physician without special equipment, and most of the patients thus diagnosed can be satisfactorily handled without access to special facilities. A person who is thus found to have migraine or flat feet or impetigo does not need a group of specialists or a well equipped institution. Or the patient may have a common cold and just have to stay in bed at home for a day or so. It would be unfortunate if the elaborate facilities of a large institution had to be called on under such circumstances. The human body is still subject to simple illnesses even as the soul is still sensitive to simple pleasures. Why clutter up institutions with such patients? And can they not be more satisfactorily handled by a family doctor in his office or in the patients' homes? Why not use institutions and groups of specialists as the adjuncts which they are and not as the totalities which many regard them to be?

The problem, then, is to educate the doctor so that he will be informed of the modern advances of medicine, to keep him informed of the continuing advances, to give him free access to facilities for employing these advances, and finally to make it possible for the sick or potentially sick patient to purchase what the family doctor, thus made fully adequate, can supply. Every phase of the problem is equally indispensable.

A final point:

A widespread academic and clinical organization such as is envisaged in the Tufts program can demand of its affiliated family doctors, as well as of its institutional staffs, not only the highest scientific standards, but such ethical standards as to assure the practice of medicine on its traditional high plane.

SUMMARY

It is indicated that a sufficiently comprehensive post-graduate medical program can encompass most of the noneconomic aspects of the problem of the distribution of good medical care. Such a plan is being developed at Tufts through the Bingham Associates Fund. The program functions through clinical hospital affiliations, hospital extension services and post-graduate courses. Within the framework of these broad groupings there

exist many opportunities for further extensive development and experimentation. The clinical organization involves the setting up of a number of hospitals over widely separated areas whose total function is that of a single coordinated and balanced institution. Medical institutions and groups of specialists are viewed as adjuncts to the general practitioner, who is thus placed in a role of major importance. It is believed that the sick or potentially sick patient can best be cared for as an individual under such an arrangement.

30 Bennet Street.

DISTRIBUTION OF NEGRO PHYSICIANS IN THE UNITED STATES IN 1942

PAUL B. CORNELY, M.D.

Head, Department of Bacteriology, Preventive Medicine and Public Health, Howard University School of Medicine

WASHINGTON, D. C.

The distribution of Negro physicians in the United States has not been the subject of study since 1932, when Lewis,¹ using the directory of the American Medical Association and through questionnaires to various medical schools, investigated this subject. During the early part of 1942 the opportunity for such study presented itself again. Col. Campbell C. Johnson, executive assistant to the director of the Selective Service System, was desirous of obtaining information concerning the present distribution of Negro physicians in the United States for use in connection with certain specific problems arising in the Selective Service System. As a member of the National Medical Advisory Board of this agency, I was asked to develop a plan whereby this information could be obtained. The following procedure was suggested and subsequently used:

1. The mailing list of the National Medical Association, a national organization of Negro physicians, was first obtained and checked with various lists available from medical schools, voluntary health organizations and the Julius Rosenwald Fund.

2. After this had been completed, a list of Negro physicians was compiled for each state and sent either to the president of the component state medical society of this association or to a prominent Negro physician in the state, who was asked to check the list for completeness, taking into consideration the deaths, the recent additions and those who had left the community to practice elsewhere. The cooperation from this group was excellent. In all instances except one the lists were returned promptly and properly corrected.

3. In view of the possibility of many inaccuracies in such an approach, a request was made of the Procurement and Assignment Service to furnish, if possible, a list of Negro physicians who had filled the questionnaire sent by them to all physicians during the latter part of 1941 and the early months of 1942. This agency, as soon as it had completed its analysis, sent this information.

4. Then the two lists, namely the corrected one from the various states and that of the Procurement and Assignment Service, were checked against each other, name by name, and in this manner it was possible to obtain a final composite list which for all intents and purposes included the names of practically all Negro

physicians practicing in the United States as of 1942, the year during which the major part of these investigations was done. The checking of these lists was facilitated by the fact that, in addition to the names, the street address for each physician was available.

5. After this complete list had been obtained, the material was analyzed in terms of the distribution of Negro physicians according to the Negro population in the various regions, states and cities in the United States.

It is believed that, although there may be a few inaccuracies, this analysis represents the normal distribution of Negro physicians for the year 1942 because very few Negro physicians had been inducted into the armed forces during the latter part of 1941 and the early portion of 1942. Most of the Negro medical men who are now in the Army have been called since the latter part of 1942. Furthermore, most of those who have been called have come from the northern area, leaving the distribution in the South fairly stable. Even so, up to Nov. 8, 1943, according to a release from the Bureau of Public Relations of the War Department,² only 395 Negro physicians, or a little better than 10 per cent of all Negro physicians, were serving in the United States Army. Thus the impact of the war has not caused the tremendous dislocation in the body of Negro physicians which it has had on the mass of their white colleagues.

DISTRIBUTION OF NEGRO PHYSICIANS ACCORDING TO THE MAJOR SUBDIVISIONS OF THE UNITED STATES

It is rather fortunate for comparative purposes that the Lewis study, already mentioned, and data published by the American Medical Association³ also for 1932 are available, so that it is possible to evaluate what has happened to the distribution of Negro physicians during the decade 1932 to 1942. According to our analysis, in 1942 there were 3,810 Negro physicians serving a Negro population of almost 13 million Negroes, based on the 1940 census. Whereas the Negro population increased about 8 per cent during 1930 to 1940, the number of Negro physicians decreased from 3,985 in 1932 to 3,810 in 1942, or about 5 per cent. Such a decrease has not been noted for the number of physicians as a whole; rather there has been a very definite increase. According to the American Medical Association, in 1931⁴ there was a total number of 156,339 physicians as compared to 176,191 in 1942,⁵ showing an increase of 12.1 per cent and thus comparing favorably with an increase in the total population of 7.2 per cent during 1930-1940.

The decrease in the number of Negro physicians during this decade may be explained solely on the basis of what took place in the field of medical education for Negroes in this same period. Figures obtained from the various educational numbers of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and presented in table 2 for 1928 through 1938 (the last year for which data concerning Negro students is available) show that up to 1935 approximately 100 Negro physicians were graduated yearly, but after that year the figures gradually decreased until by 1938 only 61 Negroes were graduated from all medical schools. On the basis of figures obtained for subsequent years since 1938 from Howard University and Meharry medical

5. Report of Committee on Medical Preparedness of the American Medical Association, J. A. M. A. 119: 651 (June 20) 1942.

Miss Doris O. Christmas, secretary to Col. Campbell C. Johnson, and Miss Norma Pinkney, graduate student in social work, gave valuable aid in this investigation.

1. Lewis, J. H.: Number and Geographic Location of Negro Physicians in the United States, J. A. M. A. 104: 1272 (April 6) 1935.

schools, which educate the bulk of Negro physicians, this annual number presumably has remained about the same and this will be changed only when the classes graduated under the accelerated program begin to make their appearance in 1943. On the basis of estimates of the American Medical Association it can be stated that from 2 to 2.5 per cent of physicians will die yearly. If this applies with equal force to the Negro, then from 80 to 100 colored physicians die yearly and therefore up to 1935 Negro physicians graduated in numbers which exceeded by slight margin those dying. However, since that year the number has been insufficient for replacements and thus the total number of Negro physicians had gradually declined. Parenthetically, it may be stated that the figure 3,810 must have a substantially high degree of accuracy, since an estimate made purely on the basis of the estimated number of Negro physicians dying and the number graduating yearly during 1932 and 1942 results in a figure of 3,860, which is quite a close approximation to the actual figure.

Referring to table 1 again, it is noted that decreases were general throughout all areas of the United States with the exception of two divisions in the North, namely the Middle Atlantic, where there was an increase of almost 30 per cent, thereby exceeding the population increase of 20.5 per cent, and the West North Central, where the figures were approximately 10 and 6 per cent respectively. Thus the North as a whole shows an increase of 7.5 per cent in the number of Negro physicians as compared to decreases of 12.1 per cent and 14.8 per cent respectively for the South and the West. The explanation for this is, of course, obvious. Negro physicians, like all physicians, have had a tendency to locate in the large urban centers of the North, and this was even more true during the depression years. It must be kept in mind however that, even though there

The number of Negro physicians in this region decreased from 525 to 393, or approximately 25 per cent.

There is at present in the United States 1 Negro physician for every 3,377 Negro individuals. This is approximately 4.5 times the proportion existing in the United States as a whole, where we have 176,191 physicians serving approximately 132,000,000 persons, or a ratio of 1 to 750. Even when the ratio of 1 physi-

cian to 1,500 individuals,⁶ which has been suggested as the wartime minimum for civilian safety, is accepted, the situation in the Negro population is at a serious disadvantage. This is even more striking when the various regions are considered. The South, with over 75 per cent of the Negro population, has the most unfavorable ratio with 1 Negro physician for every 4,913 colored persons, and in this area the West South Central subdivision reaches the lowest level, with 6,171 Negroes for each physician of this racial category. On the other hand, the most favorable position obtains in the West and East North Central areas with respective ratios of 1 to 1,151 and 1 to 1,517. It is indeed striking to note that in these two areas with 1,420,318 Negroes there are 1,010 physicians serving them, while in the whole Southern area with 9,904,619, or seven times this population, there are only 2,018 Negro physicians, or twice the number in the West and East North Central areas combined. Another disadvantageous comparison is seen between the West North Central and West South Central areas. In the former there are 350,992 Negroes with 305 Negro physicians, while in the latter there are seven times as many Negroes with only 88 or 29 per cent additional doctors.

DISTRIBUTION OF NEGRO PHYSICIANS ACCORDING TO STATES

The conditions existing in the various states reflects in an individual fashion what has already been noted for regions and larger subdivisions. The statement of a recent writer well depicts what has occurred among Negro physicians in these communities. "The trend," said he, "during the past twenty years has been for the states rich in physicians to become richer and the poor poorer, largely because of the preference of new graduates for location in the medically wealthy states." Even though there has been a decrease in the total number of Negro physicians in the United States, an examination of table 3 adequately confirms this statement. In the twenty-one states located in the North with favorable ratios, all but five show either no change or a definite increase in the number of physicians during the period 1932-1942, and in most of these instances the increase was out of proportion to the increase in population. The increase varied from 5.7 per cent in Kansas to 48.6 per cent in New York. On the other hand, in the seventeen Southern states all but three showed decreases ranging from 1.1 per cent for Virginia

TABLE 1.—Distribution of Negro Physicians and Population and Population per Physician According to Major Geographic Divisions

was an increase in the number of physicians in the North, this was only apparent, since the population percentage increase in this area during 1930-1940 was double that of the physicians. Another point which should be emphasized is the fact that the most significant decrease occurred in the West South Central area, a section which contains one fifth of the Negro population and therefore one least able to afford it.

6. Hearings Before a Subcommittee (Peterson Committee) of the Committee on Education and Labor of the United States Senate, Seventy-third Congress, Second Session, on S. Res. 24, Washington, D. C., Government Printing Office, 1943, pp. 2, 16, 62.

to 45.8 per cent for Arkansas. In the three states which did not show decreases, namely Maryland, North Carolina and Alabama, the first two have stood high among the Southern states when per capita income was considered, while the favorable position of Alabama is due to the location therein of a large Negro Veteran Administration Facility, which attracts a number of Negro physicians.

The population per physician ratio in the various states again presents the same pattern, considering only the states and excluding the District of Columbia. All the Northern states have a population ratio which is better than the national average. These range from 1 Negro physician to 1,002 Negroes in Missouri to 1 to 3,309 in Minnesota. If we accept the ratio of 1 to 2,000 as a rather favorable one, thirteen of the twenty-one in this group fall in this category. As a matter of fact,

all the states except one, namely Minnesota, which has a rather small Negro population, have a ratio of better than 1 to 2,200 individuals. The Southern states, with the bulk of Negro population, show a situation of much concern to the public health of this group. Of the seventeen states, only five had ratios better than the national figure, but none reached a level below 1 to 2,000. The proportion in these states varied from 1 to 2,068 in Tennessee to 1 to 18,527 in the state of Mississippi, where almost one tenth of the Negro population of the United States resides. The six states with the most unfavorable ratios may be listed as follows: Mississippi 1 to 18,527, South Carolina 1 to 12,152, Louisiana 1 to 8,666, Arkansas 1 to 8,320, Alabama 1 to 7,866 and Georgia 1 to 7,134. According to Lewis in 1932, this disfavored group was made up of the states of Mississippi, South Carolina, North Carolina, Alabama, Louisiana and Georgia. Thus it is seen that during the ten year period only North Carolina has been able to escape from this group, to be superseded, however, by Arkansas.

The state of Mississippi, it is thus seen, has stood in an unfavorable light for a number of years, and its situation appears to grow worse. The Council on Medical Education and Hospitals,⁸ in a study made in 1938 of the hospital and medical care in Mississippi, showed that the total number of all physicians has shown an almost continuous decline since 1904, so that in 1938 there was 1 physician to 1,353 persons. Thus the condition among Negroes is only a graver reflection of that for the state as a whole. Of the eighty-two counties, fifty-six had no Negro physicians and seventeen of these had populations of 10,000 or more Negroes. The extreme example according to the report was Sunflower County, where there were 46,646 Negroes with only 1 Negro physician. The present situation among Negroes in Mississippi may be explained in part by the fact that the per capita income of this state is among the lowest in the Union and because the opportunities for professional growth and advancement are lacking. For instance, the hospitals in Mississippi which admit Negroes number five with only 112 beds. Such conditions would certainly fail to attract recent young Negro graduates.

DISTRIBUTION OF NEGRO PHYSICIANS ACCORDING TO CITIES

The concentration of physicians as a whole in large cities is a phenomenon which has been noted in this country for many years, and this is reflected in the Negro physician group as shown in table 4. This is seen from two points of view. First, when the percentage which each city's Negro population is to the total Negro population of the state is compared to the percentage which the number of Negro physicians in that city is to the total of the whole state, it is noted that in all instances but four, North and South, the figure for the latter is higher. The difference between the percentage of concentration of population and that of physicians ranges from 1.3 to 37.6. New Orleans shows the greatest disparity, for although it has only 17.5 per cent of the Negro population of the state it contains 55.1 per cent of the Negro physicians. In the four states which do not show this relationship

8. Hospital and Medical Care in Mississippi, Report of the Council on Medical Education and Hospitals, J. A. M. A. 112: 2317 (June 3) 1939.

the differences, however, are small, ranging as follows: Memphis 3 per cent, Cleveland 1.4 per cent, Cincinnati 2.7 per cent and Indianapolis 6.2 per cent. A second expression of this concentration is seen in the fact that for the first time in this analysis it is noted that there are not the great differences between the ratios of the North and South, as shown by the fact that the average for the ten Southern cities was 1 physician to 1,862 persons as compared to 1 to 1,464 for the ten Northern cities. In only three Southern cities, namely Birmingham, Ala., Houston, Texas, and Jacksonville, Fla., were the ratios higher than the national average of 1 to 3,377.

When all cities are compared irrespective of regions, it is noted that the greatest concentration of Negro physicians is to be found in Washington, D. C., and St. Louis, where the proportions of 1 to 743 and 1 to 766 persons respectively are equal to the oft quoted national ratio of 1 to 750 for all physicians in the United States. Such decided concentrations may be explained

TABLE 4.—*Distribution of Negro Physicians and Population and the Population per Physician in Cities with 50,000 or More Negroes*

10 Southern cities	1,006,534		580		1,862
10 Northern cities	1,562,165		1,067		1,464

by the fact that in addition to offering good economic opportunities these two cities have two important Negro medical centers which combine to attract many recent graduates. In Washington, Howard University Medical School, which graduates close to 50 per cent of the Negro physicians in this country, and Freedmen's Hospital, with over 500 beds, are to be found, while in St. Louis the second largest of all Negro hospitals, Homer G. Phillips', a municipal institution with over 700 beds, is located. As a matter of fact, the opportunity for professional advances found in the availability of hospitals explains to a large extent the greater concentration of Negro physicians in Northern as compared to Southern cities. The lowest ratio of physicians on the other hand are to be found in the two Southern cities of Birmingham, Ala., and Houston, Texas, where the proportion of 1 to 5,734 and 1 to 4,110 respectively prevail.

Little has been said about the distribution of physicians in the Mountain and Pacific states and cities. The reason for this is obvious. According to the 1940 census there were only 170,706 Negroes in the West, and

almost 75 per cent of these lived in California. Thus throughout the other ten states comprising this area Negro population groups are small and not particularly significant. However, a word or two should be said about California. During the decade 1930-1940 this state showed a rise of 53.4 per cent in its Negro population, but the number of Negro physicians showed a decrease of 9.3 per cent. However, because in 1932 it stood fourth among the states with a ratio of 1 physician to 1,081 it continued to maintain a better than average ratio in 1942 with 1 Negro physician for every 1,828 Negroes. The bulk of Negro physicians is centered, as would be expected, in Los Angeles. Fifty of the 68 physicians are located in this city, thus giving a ratio of 1 to 1,275 persons and placing it fourth among the twenty cities with populations of 50,000 or more Negroes.

COMMENT

It is seen from this analysis that the availability of Negro physicians to serve the Negro population is not sufficient to render minimum adequate medical care. This was true during 1942 before the impact of the war was felt and therefore is of particular concern during the war period and will be of even greater importance when the war has ceased and various plans to give more adequate medical care for all people are being considered.

Let us then discuss certain aspects which have a bearing on this problem. At a meeting held Feb. 17, 1943, which consisted of representatives of the Army, Navy, National Medical Association, National Selective Service System and Procurement and Assignment, the following principles were agreed on because of the inadequate ratio of Negro physicians to population in the United States, and particularly in the South:

1. That only a total of 500 Negro physicians would be called for Army services, so that medical care to the civilian population would not be too greatly disrupted.

2. That this number would be called by the end of 1943 and would be taken primarily from the large cities of the North, where there was a greater degree of concentration of Negro physicians.

3. That after 1943 there would be needed a replacement number of from 40 to 50 physicians yearly for the armed services and that these would be taken solely from the group of physicians who were just finishing or about to finish their internships.

From this it is seen that two or three results will eventuate: First, at the end of 1943 the total number of Negro physicians will have been reduced to approximately 3,500, taking into consideration those graduating in 1942 and 1943. Secondly, according to Lawlah,⁹ with the accelerated program and increased enrolment in the two Negro medical schools approximately 530 medical students will graduate every three years; but during that period, if the war is still present, a replacement number of approximately 150 will have been used and an additional 250 to 300 Negro physicians will have died, so that only about 60 to 80 Negro physicians will be added to those in civilian practice by 1946 and every three year period thereafter until the cessation of the war. Thus the ratio of Negro physicians to Negro population for many years after the war will be extremely unfavorable, and some solution will have

9. Lawlah, J. W.: How the Facilities of Our Medical Schools Could Be Enlarged to Meet the Prospective Shortage of Negro Doctors, *Negro Health News* 11:3 (Jan.-March) 1942.

to be formulated whereby many more Negro students will be trained in medicine.

It seems to me that the solution will have to be met through a number of pathways: First, for many years after the war, fellowships, scholarships or subsidies will have to be made available to Negro medical students so that the two Negro medical schools will continue to use their facilities at full capacity. If this is not done it is possible that the number of graduates from these two schools will sink again to a total of about 70 to 80 per year. Secondly, the seventy-five medical schools other than Howard and Meharry will have to assume a more liberal attitude and admit a larger number of Negroes to their classes, so that instead of graduating 8 or 10 yearly as they have during the past several years this will be increased to 40 or 50. Finally, it appears that Southern states and communities will have to develop a program of subsidization whereby Negro youths of promise will be chosen and sent to medical schools at the expense of the community, state or some foundation, with the understanding that these individuals will return to their respective state as soon as they have completed their medical training. The Commonwealth Fund has already experimented in this field with white physicians in Mississippi. These are three possible avenues of approach which will have to be considered in any postwar plan for better medical care for all people.

SUMMARY

1. A study of the distribution of Negro physicians in the United States for the year 1942 was undertaken and compared with a similar study made in 1932.

2. There has been a decrease in the total number of Negro physicians in the United States during the decade 1932-1942 of 5 per cent, although the Negro population has increased by about 8 per cent. This decrease has been felt more intensely in those areas which already were medically poor.

3. In 1942 there were 3,810 Negro physicians, or 1 to 3,377 Negroes. This ratio is less than one fourth that of 1 to 750 for all physicians in the United States. Furthermore, this ratio covers wide variations from 1 to 1,151 in the West North Central area to 1 to 6,171 in the West South Central area.

4. The South as a whole shows the lowest ratio, and this is reflected in the individual states. All Southern states, with the exception of five, showed ratios which were lower than the national average.

5. Negro physicians, as all physicians, have a tendency to concentrate in large cities. This applies with equal force in the North and South.

The Hysterical Constitution.—The hysterical constitution may be defined as a psychoneurotic state in which "ideas control the body and produce morbid changes in its functions" (Möbius). It is often found in neuropathic families. While symptoms may be latent for long periods, they may be manifested during adolescence, following emotional disturbance of any sort, traumatism or other causes. Formerly thought to exist only in women, it has been found to occur quite as often in men. Hysteria is characterized by stigmata which may be sensory, motor or psychic. The sensory stigmata may be found in any of the five special senses. The skin anesthetics are characterized by their distribution which do not correspond to normal sensory nerve areas and by the changeability of their extent, character and position. They frequently follow a suggestion made by the examining physician.—Davis, John E.: *Principles and Practice of Rehabilitation*, New York, A. S. Barnes & Co., Inc., 1943.

Clinical Notes, Suggestions and New Instruments

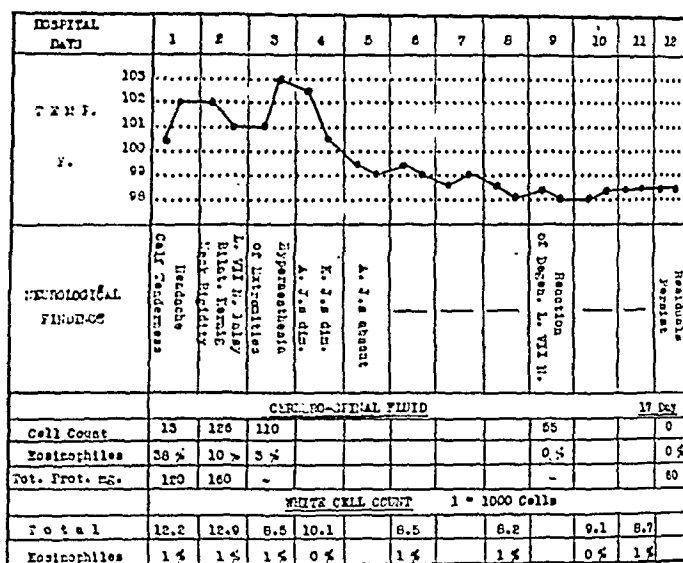

EOSINOPHILIA IN CEREBROSPINAL FLUID

LIEUTENANT COLONEL J. L. APPLEBAUM
AND

MAJOR L. E. WEXBERG
MEDICAL CORPS, ARMY OF THE UNITED STATES

An opportunity to study a neurologic case in which there were eosinophilic granulocytes in the spinal fluid brought to our attention the comparative rarity of this finding and the paucity of reports in the American literature.

The first observations of eosinophilia in the cerebrospinal fluid were published independently in 1913 by Grund¹ and Waterhouse.² In both cases cerebral cysticercosis was the clinical diagnosis, and confirmation was established by postmortem studies. Among other cases described there were contributions by Schenk,³ Buscaino,⁴ Rizzo,⁵ Ugurgieri,⁶ Busse,⁷ di Maggio,⁸ Lange,⁹ López Albo and Feijóo,¹⁰ Canziani and Nobile¹¹ and Graña and Schenone.¹² The evaluation of this finding for the diagnosis of cerebrospinal cysticercosis has been discussed by

Temperature range, neurologic findings, spinal fluid studies and white cell counts.

Canziani and Nobile¹¹ and by López Albo and Feijóo,¹⁰ who agree that, whenever detected, it is practically pathognomonic. On the other hand, Lange⁹ and Monteiro and Salles¹³ attribute

Captain Joel Shrager, M. C., and Estelle Hall, medical secretary of Gorgas Hospital, rendered assistance.

From the Medical Service of Gorgas Hospital, Ancon, C. Z., Col. H. C. Dooling, chief of the medical service.

greater importance to the complement fixation test. It is also worthy of note that abnormal percentages of eosinophils in the blood were absent in a number of these cases.

Cerebrospinal eosinophilia in conditions other than cysticercosis has been reported on rare occasions in neurosyphilis by Mosny and Harvier¹⁴ and Mari.¹⁵ The finding has also been detected in experimental serum meningitis (horse serum) and schizophrenia treated with intraspinal malarial blood injections.¹⁶ Busse⁷ found sporadic eosinophils in the spinal fluid in a case of cerebral echinococcal infection. It appears then that for clinical purposes neurosyphilis and cystic disease of the central nervous system due to the echinococcus are the only other diseases to be considered in the differential diagnosis.

REPORT OF CASE

E. S., a white man aged 25, was admitted to the hospital on June 28, 1943 because of sore throat, malaise, general aches, feverishness, frontal headaches and cramps of the legs. The family history and past history were irrelevant. The onset of his illness was acute, following a 21 mile hike on the day before admission. The patient was well developed. There were moderate pharyngitis and tonsillitis, and tenderness of the calf muscle. Complete blood count, urine analysis, stool examination and blood serologic examination gave results within normal limits.

His course was stormy for a few days, as neurologic complications set in, as shown in the composite chart. On the day following admission his headache was accentuated, and moderate nuchal rigidity, bilateral Kernig sign and complete paralysis of the left facial nerve were detected. At this time a lumbar puncture was performed, which revealed 13 cells per cubic millimeter in the spinal fluid, 5 eosinophils and 8 lymphocytes. Culture of the nose and throat was negative. Signs and fever persisted and there was no response to chemotherapy (sulfadiazine). On the next day, June 30, there were 126 cells in the spinal fluid with 10 per cent eosinophils, 86 per cent lymphocytes and 4 per cent polymorphonuclear cells. Additional tests of the fluid revealed that the total protein was 160 mg. per hundred cubic centimeters, dextrose and chlorides were normal, the Wassermann and colloidal gold tests were negative, and smear and cultural studies were negative. Other examinations, including frequent blood counts, stool examinations, urine analyses, electrocardiographic studies, an x-ray film of the chest, eyeground examinations and agglutination tests, gave normal results. The eosinophil count of the peripheral blood was always within normal range. On July 1 there were 110 cells in the spinal fluid with 3 per cent eosinophils. Then he developed definite sensory disturbances of the extremities (hands and feet) and it was noted that the patellar reflexes were diminished and the achilles reflexes were absent.

His general condition gradually improved and no cells were found in the spinal fluid on July 14. However, he continued to present the neurologic residuals of left facial paralysis, sensory disturbances of the extremities and diminution of patellar and achilles reflexes until the date (July 31) of his discharge to a hospital in the United States.

COMMENT

The diagnosis of cerebrospinal cysticercus meningitis was the dominant consideration. Localization of the process at the base of the brain, which is rather common in cysticercosis, accounted for the facial nerve paralysis, and spinal meningitis was the basis for the rest of the neurologic symptoms. Spinal localization is rare, but it has been described.¹⁰

Neurosyphilis and echinococcal infection were more remote possibilities. There was no sign suggestive of syphilis, which was virtually ruled out in an acute meningitic process by negative serologic findings in the blood and spinal fluid. As

for echinococcal infection, the clinical picture is inconsistent with this condition, which usually produces the syndrome of brain tumor due to a rather large single cyst located in the cranial cavity. In view of all these facts it is believed that cerebrospinal cysticercus meningitis fulfills acceptable criteria for the diagnosis.

Cysticercosis of the central nervous system may be more frequently encountered than is generally recognized. With this possibility in mind, certain laboratory procedures are recommended: (1) sedimentation of the cerebrospinal fluid in search of eosinophils, (2) precipitin tests¹⁷ and intradermal tests¹⁷ in suspected cases.

SUMMARY

1. A case with the findings of eosinophilia in the spinal fluid and manifestations of acute cerebrospinal meningitis was observed.

2. The syndrome closely resembled cases of cysticercosis of the central nervous system previously described and was considered the most probable diagnosis.

3. The condition is more common than is generally recognized and in suspected cases such special procedures as sedimentation of the spinal fluid in a search for eosinophils and intradermal and precipitin tests are recommended.

A NEW APPARATUS FOR THE ADMINISTRATION OF 95 PER CENT OXYGEN

MEYER SAKLAD, M.D., and ALEXANDER M. BURGESS, M.D.
PROVIDENCE, R. I.

The use of 95 per cent oxygen for the removal of nitrogen from tissue spaces and from certain cavities and viscera was advocated by Fine and his associates¹ in 1936. These investigators showed that replacement of nitrogen in the alveolar air by oxygen was followed by the reduction in the nitrogen tension in the circulating blood and the passage into the blood of a large proportion of any nitrogen trapped in the distended

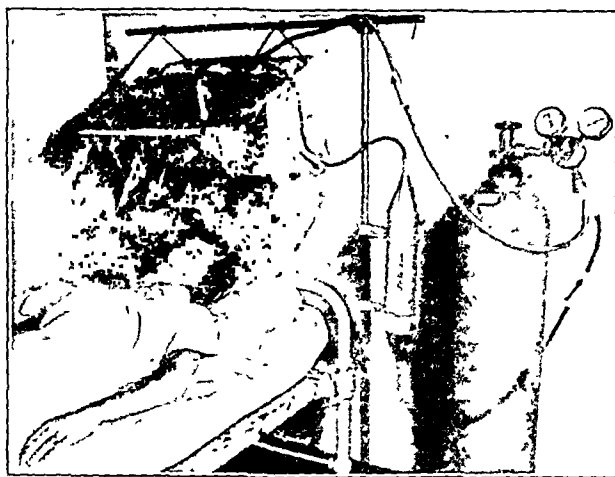

Fig. 1.—The entire apparatus in use on a patient

small intestine or in tissue spaces. During the past seven years this principle has been employed at the Rhode Island Hospital in the more severe cases of paralytic ileus as well as in a few cases of subcutaneous emphysema. The method has also been used to reduce the headache following acroencephalography. A short report of our earlier results was published with Dr. Palmer Congdon.²

2. Congdon, P., and Burgess, A. M.: Clinical Experience with 95 per Cent Oxygen in the Treatment of Abdominal Distention and Other Conditions. New England J. Med. 221: 200 (Nov. 24) 1939.

In this work the apparatus for administering 95 per cent oxygen was the closed box technic described by one of us.³ We have attempted also to use high concentrations of oxygen by one of the masks in common use (B. L. B. or O. E. M.) but have found that with neither of these is it possible to maintain a concentration completely satisfactory for the purpose, although at times their use has been followed by clinical improvement. In the case of the B. L. B. mask there is, even at a flow of 8 liters per minute, an appreciable degree of rebreathing with consequent carbon dioxide accumulation, and in the case of the O. E. M. it appears to be impossible to prevent

Negative Pressure at Various Flows of Oxygen

collapse of the bag on inspiration even at rates of oxygen flow as high as 12 liters per minute. In our own closed box technic, although the carbon dioxide concentration has not been found over 2.5 per cent, it has seemed to us that a better method for the removal of this gas could be devised and we

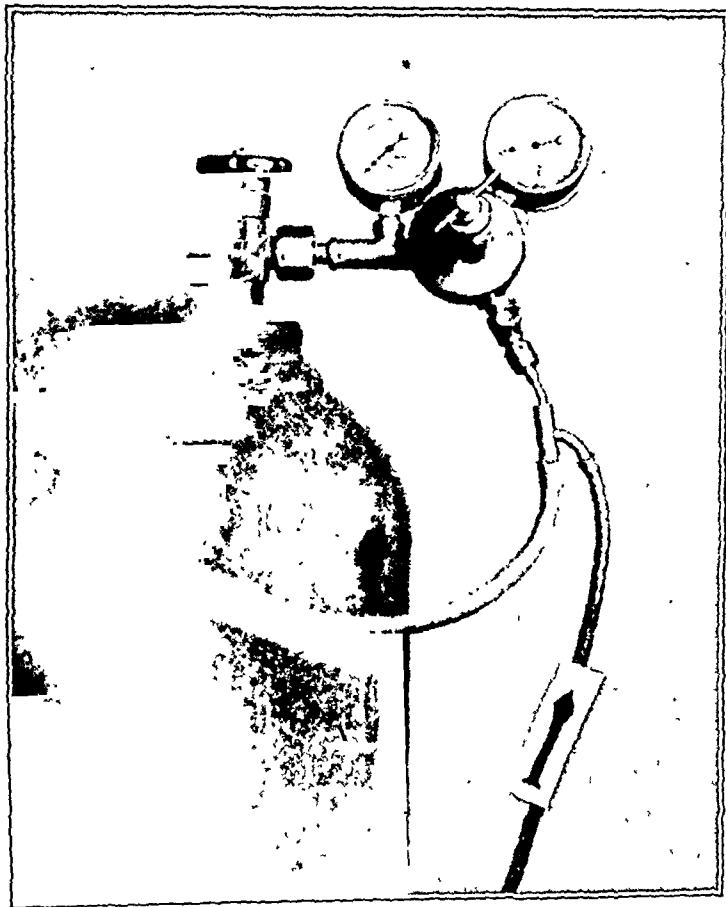

Fig. 2.—The venturi valve attached to the oxygen regulator.

have therefore developed the apparatus described herewith, following a suggestion made to us by Mr. Joseph Sears, the then head orderly in charge of oxygen apparatus.

The apparatus consists of a closed oxygen box of the usual type without the tray of soda lime that was formerly used.

3. Burgess, A. M.: Oxygen Therapy—A Modification of the Box Method for Giving 95 per Cent Oxygen, *New England J. Med.* 216: 467 (March 18) 1937.

Instead of eliminating carbon dioxide by such a tray suspended inside the box, the respired atmosphere is circulated through a cylinder of soda lime outside the box. Instead of using a motor blower, which would increase the cost and incur the hazard of fire, the injector principle is employed. As the oxygen leaves the cylinder under great pressure it is passed through

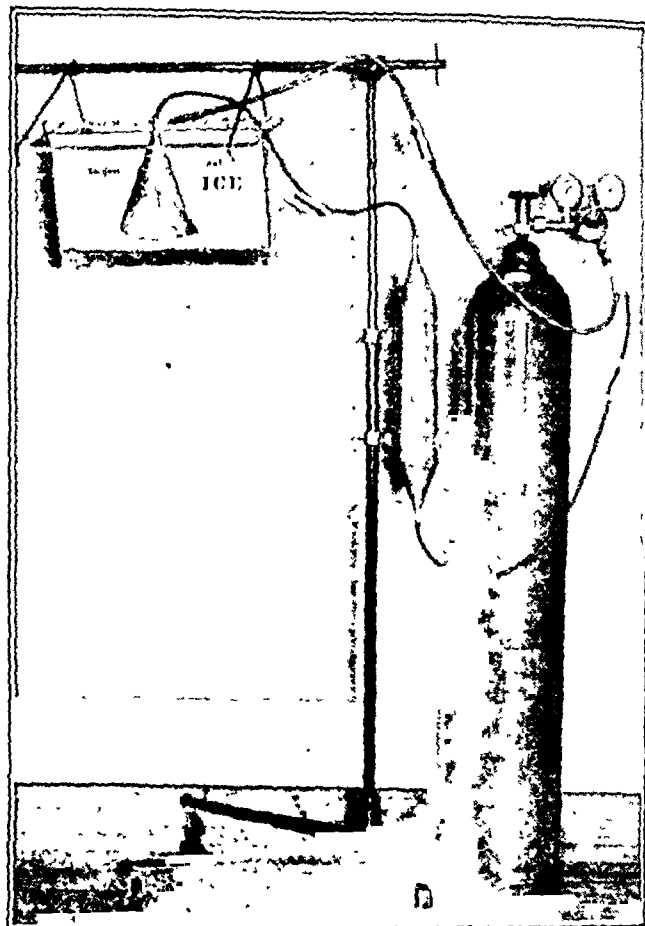

Fig. 3.—The apparatus assembled without the canopy to illustrate the recirculation of atmosphere through the cylinder of soda lime.

a venturi valve. This creates a negative pressure in a side tube. Thus the flow of oxygen, as may be noted from the accompanying illustrations, not only serves to satisfy the patient's oxygen requirements and maintain the desired 95 per cent concentration but also satisfactorily produces a circulation through the soda lime, which reduces the carbon dioxide in the box to about 1 per cent.

This venturi valve creates varying degrees of negative pressure dependent on the flow. The accompanying table gives the amount of negative pressure in inches of water at the various flows of oxygen in liters per minute.

It is hoped that the availability of this inexpensive and satisfactory method of developing and maintaining high nitrogen free atmospheres will encourage the use of this important type of therapy in conditions in which nitrogen removal from tissue may be of advantage to the ill patient.

454 Angell Street.

Thoracic Surgery—Youngest of All Surgical Specialties.—Thoracic surgery is the youngest of all the surgical specialties. It is so young that the surgeons who today concentrate their efforts on diseases of the chest are the first generation of thoracic surgeons, the men who originally did the daring surgical feats that have earned recognition for their specialty. They are perhaps the only real pioneers in surgery that the present day medical student can view in person. And if he sees one of them in action, removing a lung or a mediastinal tumor, with the great cavity of the chest opened wide and the heart and great vessels beating away in plain view, he may well regard the thoracic surgeon as unbelievably bold. For this is the most spectacular of all modern surgery.—Haagensen, C. D., and Lloyd, Wyndham E. B.: *A Hundred Years of Medicine*, New York, Sheridan House, Inc., 1943.

Special Article

EMERGENCY MATERNITY AND INFANT CARE PROGRAM

FOR THE WIVES AND INFANTS OF MEN IN
THE ARMED FORCES

MARTHA M. ELIOT, M.D.

Associate Chief, Children's Bureau, U. S. Department of Labor

WASHINGTON, D. C.

SCOPE AND PURPOSE OF PROGRAM

The Emergency Maternity and Infant Care program provides medical, nursing and hospital care for the wives and infants of enlisted men in the four lowest pay grades of the Army, Navy, Marine Corps and Coast Guard. The program became effective March 18, 1943 and is now in operation in forty-eight states, Hawaii, Alaska, Puerto Rico and the District of Columbia. By the end of the first year of operation it is expected that maternity and infant care will have been made available to nearly a quarter of a million wives and infants of enlisted men.

The EMIC program, as it is known for short, was made possible by the Congress for the primary purpose of relieving the enlisted men of worry and uncertainty as to the availability of the maternity and infant care needed by their families and how the cost of care will be met, and of assuring their wives, wherever they may happen to be living, that care will be provided through an organized program under state health departments. Those professional persons who are participating in the program may derive great satisfaction from the enthusiasm with which the enlisted men and their families have welcomed the program and from the fact that they are contributing materially to raising the morale of our armed forces. That the program does raise the morale is the judgment of Army and Navy officials and of others who are directly concerned with morale.

The program through which maternity and infant care has been made available is a wartime measure specifically planned for the duration of the war and a period of six months thereafter. The regulations of the Secretary of Labor for the allotment of funds have so defined the period of its operation. The federal and state agencies given responsibility for administration of this program must exercise that responsibility in the light of the contribution it can make to the war effort. The responsibility for planning given to the state agencies must be interpreted to mean positive action to make available, as far as is possible under the conditions in any state, the care provided under the program for any wife of an enlisted man in one of the four lowest pay grades who seeks it for herself or her infant, regardless of whether she is a resident of the state or not.

The magnitude of the emergency which this program is designed to meet is proportionate to the great number of men in our armed forces. The geographic area involved comprises all of the states and territories of the country, for from all of them enlisted men have entered the armed forces. Applications for care are currently being received at the rate of more than 30,000 a month. Many come from wives who are only temporarily resident in the state where application is made.

In the coming year it is estimated that between 300,000 and 400,000 wives of enlisted men may apply for maternity care under the emergency program and that the number of applications for medical care for infants may reach 60,000 to 80,000. The number of infants who will be given protective health service, such as general health supervision and immunization, will depend on available organized services and on funds available to amplify those services.

The effective operation of the program is important to a large number of enlisted men—approximately 87 per cent of enlisted men are in the four lowest pay grades. If it is to continue to serve the enlisted men and their families as well as possible there must be a clear understanding of the program—its scope and limitations, the services it seeks to provide and the compensation for services, the major policies and the experience and principles which underly these policies. The purpose of this report is to contribute to such an understanding.

FRAMEWORK OF ADMINISTRATION

The EMIC program had its origin and its legislative authority in the provisions of title V, part 1, of the Social Security Act. Funds for its operation have been made available through appropriations to the Children's Bureau of the U. S. Department of Labor for grants to the state health agencies for medical, nursing and hospital care of the wives and infants of enlisted men in the four lowest pay grades of the armed forces. The Secretary of Labor when establishing regulations with respect to allotment of funds to the states has required the Children's Bureau to administer the expanded program, though financed by special appropriations, under certain conditions laid down in the Social Security Act.

How the Program Works.—Any wife of an enlisted man in one of these four pay grades may apply to the state health agency for maternity care for herself or medical care for her infant during the first year of his life. Her application includes information with respect to the service connection of her husband or the father of the baby.

In accordance with provisions of state plans the physician (or the clinic or hospital) from whom she seeks care obtains an authorization to give care (usually on the same blank with the wife's application) from the state health agency's maternal and child health division. Each state health agency outlines in its state EMIC plan the specific services which the state will authorize, the rates of compensation for services and its standards to safeguard quality of medical and hospital care. These state plans are developed in accordance with the general policies of the Children's Bureau.

Local health agencies cooperate with the division of maternal and child health of the state health agency through services rendered by the local staff in child health conferences, antepartum clinics, mothers' classes, public health nursing service and, to varying degrees, in sharing in the handling of applications and authorizations. The development of the state plan, its administration and operation are responsibilities of the state health agency.

The funds are allotted to the states by the Secretary of Labor as the appropriation act of Congress requires. Under the provisions of the act the Children's Bureau is responsible for review and approval of the state plans

to establish that they do in fact assure proper and efficient operation of the plans and make provision for maternity and infant care (medical, nursing and hospital services) in accord with the intent of Congress. So that its responsibilities may be carried out consistently, with as little confusion or uncertainty as possible, and that the state agencies may be informed in advance as to the standards it would use in approving state plans, the Children's Bureau formulated certain administrative policies and minimum requirements. In many instances state health departments have been able to go beyond these minimum requirements and have established within their own states higher standards than those formulated by the federal agency. The movement of wives from state to state as their husbands in the armed forces are transferred from one military establishment to another creates interstate administrative problems and a need for some uniformity among states as to services provided and payment for services. The policies of the Children's Bureau have been intended to meet some of these needs.

MEDICAL AND RELATED SERVICES OF THE PROGRAM

The program is intended to provide the various services needed for maternity and infant care, payments being made directly to physicians, hospitals, nurses or others for service. The funds are not to be used, however, to replace similar services otherwise available without cost and without financial investigation, such as those provided by the Army or Navy, or state and local health agencies.

Medical, Hospital and Nursing Service.—The service to wives and infants of enlisted men for which state plans provide payment are the following:

1. Medical services (and, when necessary, surgical services) provided by physicians for complete maternity care (a) throughout pregnancy, labor and six weeks post partum, (b) for major intercurrent conditions occurring during but not attributable to pregnancy and (c) for the care of sick infants
2. Consultant services of specialists
3. Hospital care for maternity patients and sick infants whenever needed and for whatever period of time necessary
4. Immunization of infants against smallpox, diphtheria and whooping cough
5. Bedside nursing care for maternity patients and infants when requested by the attending physician.
6. Other services such as blood for transfusion and ambulance service when requested by the attending physician

The plan provides, then, not only for the services and facilities ordinarily required but also for the more seriously ill patients and for medical and surgical complications. There are no restrictions with respect to place of residence, race, color or creed.

Related Health Services.—State and local health departments make available various maternal and child health services to supplement the care provided by the emergency program. All patients under the program are referred to local health agencies for public health nursing service, wherever they are available. The advice and assistance of public health nurses in both the antepartum and postpartum period are of great value to many of these patients, among whom a large number are still in their teens and are living away from their homes. Many of these enlisted men's wives, confronted

with social problems which relate either to their own maternity care or to the care of their infants, are unfamiliar with the resources of the community in which they happen to reside and often unaware of channels of assistance available to them.

Physicians who have attended any considerable number of these young wives of servicemen know that they are oftentimes living under difficult conditions. They are often strangers living in strange places. Many are burdened with financial, social and emotional problems. Physicians cannot be expected, especially in these times of stress, to assume responsibility for more than the direct medical services which the patient requires. Arrangements for hospital services, special nursing services, care of the postpartum mother after early discharge from the hospital, and other phases of care which may be necessary, are the responsibility of state and local health agencies. The state health agencies are finding it helpful to make available medical-social personnel who can work in cooperation with state and local welfare departments and other agencies, such as the American Red Cross, the Army Emergency Relief and Navy Relief Society.

The enlisted men may thus be more secure in the knowledge that, when their wives submit an application for care, the state health department assumes responsibility not only to pay for the care but to see that all appropriate and necessary services are actually made available to the patient if possible.

MAINTAINING QUALITY OF MEDICAL CARE

The program has been carefully considered and developed with the purpose of preserving and, so far as possible, improving standards of quality of care. The Children's Bureau is fully in accord with the American Medical Association, the Academy of Pediatrics and other professional associations in viewing the question of quality of medical care as of paramount importance, but it believes that under a system of cash allowances to soldiers' wives, recommended by the American Medical Association, there would be little or no opportunity to influence the standard of care for these patients.

Because it is designed to provide service, however, the EMIC program can set up certain minimum safeguards for the maintenance of standards of medical, nursing and hospital care. Obviously, still greater safeguards could be provided if the shortage of physicians and nurses did not exist, if there were a better distribution of obstetricians, pediatricians and hospitals or if state agencies would or could provide full time physicians in areas where there is a shortage. Nevertheless the very existence of the program does make possible certain services that tend to improve the quality of care.

Medical Care.—The program makes provision for two services which, if used as intended, will aid materially in maintaining and improving the quality of care, namely consultation by specialists and special services such as bedside nursing care in a home or special nurses in a hospital, x-ray service, blood for transfusions and ambulance service. Through this provision physicians are relieved from all concern that the patient's resources will not permit these services. The patient herself, or the infant's mother, and the husband in the armed forces gain the assurance that financial consideration will not limit the medically necessary service or impose restrictions on complete and satisfactory care.

The program places no restraint on the wife of an enlisted man by expecting her to pay toward the cost of her care or that of her sick infant. Even the first visit at the time of her application for care and emergency care for herself or her sick infant will be paid for. There is no waiting period. This should encourage early care for a mother or a sick baby.

The program further provides that state health agencies may employ physicians full time or part time to meet the needs of areas where a shortage of physicians affects the amount and quality of care.

Hospital Care.—Under the EMIC program the state health departments have established certain requirements or standards for hospital care of infants and maternity patients, based on minimum requirements set up by the Children's Bureau as a guide for its use in approving state plans. Hospitals which are unable to meet these standards are advised by the state staff how they may succeed in doing so. Especially at this time, when hospitals are crowded and in many instances understaffed, physicians recognize the importance of energetic efforts to maintain reasonable levels of good practice for the safety of their patients. The emergency program has helped in this direction.

Hospitalization of maternity patients rather than home delivery is, of course, not always a guaranty of better standards of care. When coupled with an earnest attempt to assure maintenance and improvement of hospital standards, however, increasing hospitalization of maternity patients is generally considered a step toward improved maternity care. The percentage of maternity patients hospitalized in the emergency program thus far (86 per cent in December 1943 for all states reporting) is considerably greater than was the case for all maternity patients in the United States in 1942 (68 per cent). There is little doubt that the provision of funds for payment for care to hospitals has increased materially the hospital facilities available to enlisted men's wives and infants.

METHODS OF PAYMENT FOR SERVICE

In arriving at appropriate methods of compensation for medical and hospital service, the Children's Bureau has considered the following:

1. The Congress has made it clear that the program is not to be administered as a charity service with a "means test," nor, on the other hand, was it contemplated that the rates of payment for care should reflect specialists' rates or even the maximum rates of general practice, or that private accommodations in hospitals would be provided unless medical necessity should require it.

2. In the neighborhood of 75 per cent of all maternity care by physicians and a very large proportion of care of sick babies is in the hands of general practitioners.

3. Considerable variation in rates, both for hospital care and for medical practice, exists in different parts of the country or from place to place in the same general geographic area.

4. Payments to hospitals by public agencies have not as a rule reflected actual cost of care but an amount less than cost.

5. The amount of "red tape" for the physician participating in any public program of medical care varies greatly with the method of payment—whether on a fee for individual service basis, a case basis, a flat rate covering all care for a period of time or a salary basis.

6. Appropriate limitations on expenditures are necessary in any program supported by public funds in order that adequate control of such funds may be had.

7. Under the emergency program all physician's and hospital bills would be paid—there would be no uncollected bills for any care that had been properly authorized.

It was the responsibility of the Children's Bureau to consider these and other factors and outline a plan of payment that would be as simple to administer and leave as much flexibility in state planning as possible under the circumstances of the program, give reasonable compensation for service rendered, aid in the maintenance of care of good quality, assure reasonable economy in the use of public funds, and payment for all types of care provided under the plan even though the wives and infants moved from state to state.

Payments for Medical Service.—For payments to physicians for maternity care and care of sick infants the decision was reached that, in the circumstances, payment on a case basis was the plan that would most nearly meet the needs of the program. The way was left open for payment of part time or full time salaries and payments to clinics as occasion required. The fee for service plan was believed to be uneconomical from both a financial and an administrative point of view, except for consultation visits and payment for care of illnesses requiring only one or two visits; it certainly involves more complex procedures for reporting by participating physicians.

Some questions have been raised as to the fairness of an average case rate based on periods of time and minimum number of visits, regardless of whether the patient requires a minimum of care or a great expenditure of time on the part of the physician and the assumption of grave responsibility. It is believed, however, that the physician who has a moderate number of patients under the program will in the end be compensated reasonably under the average case rate plan. It is true that some physicians who attend only a few patients under the program may happen to have a disproportionate number of time consuming and difficult cases. However, if the average case rate plan should be abandoned in favor of a detailed schedule of fees differing for every type of service provided, "red tape" and paper work for physicians would be enormously increased, as would administrative procedures and costs.

For its use as a guide in reviewing rates of payment established by state agencies, the Children's Bureau has set up maximum rates that may be approved. The rates for medical care are inclusive of all services usually included in the type of care being given. When unusual conditions arise that are not directly related to maternity care and require home or hospital visits, as, for example, prolonged illness or a surgical condition during pregnancy, special payment may be made by the state health agency to the attending physician or to a consultant, or, if necessary, to both.

In a few states differentials in rates within the maximum for maternity care have been established for general practitioners and specialists. There is some difference of opinion among physicians, including specialists, as to whether in a public program of this nature higher rates should be paid to specialists giving routine care in cases of average difficulty or whether such specialists should be paid higher rates only for the more difficult cases requiring greater skills. This is a matter for further consideration. Perhaps the chief contribution of specialists in this Emergency Maternity

and Infant Care program will be to serve as consultants, for which type of service special rates of payment are provided.

Payments for Hospital Care.—The method and rates of payment to hospitals have been worked out on a basis which, it is believed, will provide good care and adequate accommodations for the usual case, and special accommodations and services when the medical condition requires them. In contrast to many other plans for the purchase of hospital care, the emergency program does not require that the states attempt to secure hospital care below cost. On the contrary, provision is made for inclusive rates of payment based on per diem cost as calculated by each hospital from a simple annual report of operating expenditures. For many hospitals the calculated per diem cost for this program is higher than the amount hospitals currently charge for ward service; in some the per diem cost is higher than the basic semiprivate charge. None the less, it is the calculated per diem cost which the state health departments are prepared to pay for patients hospitalized under the program. The hospital may give these patients semiprivate accommodations or private rooms when it is deemed medically desirable. The rate of payment remains the same—the calculated per diem cost.

The per diem rate paid to hospitals is inclusive of all services, salaries and other costs which form a part of the hospital's total expenditure for the care of patients, and all of these items of normal and special expenditure are included in the calculation of the per diem cost. When unusual expenditures, such as special nursing service, are not normally provided by the hospital staff and included in cost statements, extra payment may be made. The fact that the rate is in general an inclusive rate enormously simplifies the problem of administrative setup for payment for hospital services. The task of the hospital business department is also simplified, so that time and money are saved by both the health department and the hospital.

Not all hospital administrators are fully satisfied with all the details of the present method of calculation of per diem costs, nor is the Children's Bureau. With the assistance and cooperation of hospital administrators, improvements are being worked out.

THE DEVELOPMENT OF THE ADMINISTRATIVE POLICIES¹ BY THE CHILDREN'S BUREAU

In an earlier section of this report it was pointed out that the Children's Bureau has the responsibility under the law for approving state plans and that in exercising this responsibility, as well as the responsibilities with which it is charged under regulations of the Secretary of Labor, the Children's Bureau has established certain policies to serve as guides in the review of state plans. Questions often asked in this connection are: How were these policies arrived at? To what extent are they inherent in the law or interpretative of the intent of Congress? Are they fixed for the duration of the program?

To answer these and other questions similar in nature, the origin and development of the program and certain principles made clear in Congressional debate must be understood.

Origin of the EMIC Program.—The Children's Bureau's administrative policies have developed out of experience that has accumulated under the Crippled Children's provisions of the Social Security Act and the special maternity care projects under the Maternal and Child Health program. The first state program for care of wives of servicemen took shape in the state of Washington in 1941 as one of these maternity care projects under the regular Maternal and Child Health program of the state health department. During 1942 twenty-six additional individually planned state projects for servicemen's wives had been started, growing out of the need for such a program in each state. In a majority of these projects there was no "means test" or financial investigation. Many of the projects were limited to one or more areas. In all instances the projects provided for direct payments to physicians and hospitals. By late fall of 1942 still other states had requested funds for this purpose, but money available under title V, part 1, of the Social Security Act was exhausted.

The first request to Congress for additional funds in January 1943 was built up item by item in accordance with specific requests from state health agencies for funds to carry their projects through the fiscal year. Each subsequent request to Congress has been based on the experience of the states. As it became apparent that funds would be made available as needed and that Congress did not wish a "means test" to be applied, state health agencies broadened the scope of their plans to include any wife who applied in any part of the state. By June 30, 1943, forty-three states had approved plans in operation. Today all states and territories and the District of Columbia have plans in operation. Appropriations were made by the Congress during the calendar year 1943 as follows: March 18, \$1,200,000; July 12, \$4,400,000; October 1, \$18,600,000.

Participation of Advisory Groups.—Throughout its administration of the Maternal and Child Health program under the Social Security Act, the Children's Bureau has had the benefit of advice from a committee of physicians, public health officials, nurses and medical-social workers. At a meeting of the medical members of this committee on April 6, 1943 all proposed policies of the Children's Bureau for the administration of the EMIC program were reviewed, and a number of modifications were made in the light of the opinion of the committee. Policies with respect to nursing or medical-social aspects of the program have been reviewed with the appropriate members of the committee. At a meeting of the medical members of the committee in October 1943, policies were again reviewed and recommendations with respect to further modifications were made.² On the advice of the committee at its meeting in October 1943, and in view of the participation of general practitioners in the EMIC program, five additional members in private practice, three of whom were general practitioners, were appointed to the committee.

On Dec. 10 and 11, 1943, in response to a resolution of the executive board of the American Academy of Pediatrics, the Children's Bureau held a conference of official representatives of the servicemen and official representatives of the professions actually rendering this service, namely the American Medical Association, the American Hospital Association, the U. S. Public

1. EMIC Information Circular No. 1. Administrative Policies, Emergency Maternity and Infant Care Program. United States Department of Labor, Children's Bureau, Washington, D. C., 1943; J. A. M. A. 124: 241 (Jan. 22) 1944.

2. Report of Meeting of Maternal and Child Health Advisory Committee, J. A. M. A. 123: 845 (Nov. 27) 1943.

Health Service, the American Association of Obstetricians and Gynecologists and the American Academy of Pediatrics. In addition the Children's Bureau included official representatives of the Association of State and Territorial Health Officers and of five national organizations that had been active in sponsoring the program. A report of this conference has been published.³ The proposed administrative policies were reviewed again in detail and subsequently were completely rewritten. Practically all of the formal recommendations of the advisory committee made in October and of the conference in December were incorporated in the final statement. After the relation of each of the Children's Bureau policies to the intent of Congress, as expressed in the appropriation acts and in hearings and debate, was clarified no recommendations for any substantial change in overall policy were made by the conference.

To carry forward the discussion and obtain a wider opinion on the problems of health supervision and medical care of infants under the EMIC program as expressed in a recommendation at the December conference, a conference of pediatricians, health officers and maternal and child health directors was held at the Children's Bureau on Feb. 1 and 2, 1944. The responsibility of the pediatrician, the general practitioner and the child health conference in providing health supervision, the relationship of health supervision to medical care and methods of financing these services were discussed in detail. The Children's Bureau is taking all points of view into consideration in developing its policies in this field and in making recommendations as to financing the program.

THE BASIS FOR MAJOR POLICIES

Each of the meetings and conferences of the past year has in turn brought out the necessity of renewed and repeated clarification of the basis for certain major policies for the administration of this program, namely the elimination of a "means test," the exclusion of supplementary fees or charges, payment for services provided instead of cash allowances, and free choice of physician or clinic. Briefly the basis for these policies is as follows:

The Elimination of a "Means Test."—The Congress had made it clear that this program is not to be administered as if the service were "charity" but as a part of the war effort and a contribution to the morale of the armed forces. This must be interpreted to mean that no steps will be taken when the wife of any enlisted man in one of the four lowest pay grades seeks care that would raise questions as to whether or not she is entitled to the care, aside from the establishment of the service connection of the husband or father, or whether she could or should pay part of the cost. If this were not the policy governing the administration of the program, enlisted men would never be certain that their wives were "eligible" for care until a financial investigation had been completed. Many might have to leave the country without this knowledge. The primary purpose of the program would not have been achieved.

The Exclusion of Supplementary Fees and Charges.—Again the primary purpose of the program underlies this policy, namely that the serviceman should be relieved of uncertainty as to how the cost of his wife's maternity care or his infant's medical care is to be

met. The argument is sometimes advanced that if a serviceman's wife can afford to pay a supplementary fee to hospital or physician, or to pay the whole cost of either hospital or medical care, she should be permitted to use the federal funds in partial payment in order to obtain private accommodations or to be assured of the care by a physician who otherwise would not accept her as his patient.

If, under the program, physicians were to be permitted to decide after discussions with the wives of the servicemen which ones could and which ones could not make an extra payment for medical care, or if hospitals were permitted to negotiate with the wives as to whether they could or could not pay an extra amount that would make possible the more extensive use of private accommodations, a primary purpose of the program would be defeated. To all intents and purposes the physician or hospital would be applying a means test. Such a procedure would soon be universal in application, and many wives who could ill afford to pay even a small additional fee would be involved in the same type of questioning as those who could afford it.

The pay received by enlisted men in the four lowest pay grades ranges from \$50 to \$78 a month. To institute any measures for the purpose of selecting that small fraction of wives—probably less than 10 per cent—who have "outside means" and who therefore might be charged extra by physician or hospital would discriminate against the wife who does not have such "outside means"; and would be contrary to the democratic principles under which their husbands have been drafted for service in the armed forces.

Under the program the state health agency assumes the responsibility to provide, so far as it is available, all the care that may be recommended by the physician or clinic as medically necessary. The program does not provide luxury facilities, but the rates paid to hospitals are such that the type of accommodation provided may be adapted to the medical need of any patient. Application for care under this program is entirely voluntary. The program is not intended for those who wish to pay for luxury accommodations. On the other hand, care of the kind that is provided under the program is available to any wife who applies for it for herself or infant regardless of her own resources. Experience under the program shows that so far only about three fifths of all eligible wives are applying for care under the program.

Payments for Service Instead of Cash Allowances.—The legislative history of the appropriations by Congress for this emergency maternity and infant care program has made it clear that it was the intent of Congress to provide care rather than cash allowances. At the time of the passage of the special deficiency appropriation in September 1943 an amendment to the bill that would have converted the program from one of service to cash allowances, if it had passed, was defeated by a vote of 115 against, to 8 in favor. The policy of payment directly to physicians, hospitals and others rendering care is governed, therefore, by Congressional action.

It is believed that this policy should be continued if the purpose of the program is to be carried out. Were a plan for payment of cash allowances to be substituted for the present program there could be no assurance given to the servicemen that the amount of the allowance would be sufficient to meet the exceptional costs of

3. Conference on Emergency Maternity and Infant Welfare, J. A. M. A. 123: 1125 (Dec. 25) 1943.

serious illness or even all the ordinary medical and hospital costs of maternity care or care of sick infants, such as are provided under the existing program. With the best possible intentions many young wives would be likely to spend the money in ways which would fail to secure good medical care and when the allowance was used up there would be difficulty in meeting the costs of prolonged hospital care, special nursing service or consultant service for the mother or her infant. Furthermore, there would be no assurance that the cash allowance would be spent for the purpose for which it was granted, nor would there be a nationwide plan to provide for the needs of wives and infants who move from state to state. A system of cash allowances would not provide for the necessary state and community planning that is required if community health and welfare services are to be available to assist these wives in learning of resources for care and in obtaining care.

Free Choice of Physician and Clinic.—Congressional debate has made it clear that it was the intent of the Congress that the wives of servicemen should have free choice in the selection of physicians. The policies of the Children's Bureau have carried this out. No state plan for maternity care or care of sick infants has been approved that did not provide that the wife or mother might choose any physician whose qualifications met the state standards or any clinic or hospital approved by the state agency. How this principle can be applied to health supervision of infants is now being studied. Whether health supervision can be extended beyond the use of state and local child health facilities depends on several factors, including availability of physicians qualified to give care and costs of such supervisory service.

CONCLUSION

The policies of the Children's Bureau in the administration of this program are not to be regarded as fixed "for the duration," except so far as they are governed by the will of Congress. As experience indicates that they should be modified, changes will be made. Suggestions, comments and criticisms from those administering the program and those concerned with rendering the care will be welcomed and will be carefully considered by the Children's Bureau. In arriving at administrative decisions the bureau must constantly be aware of the effect that each may have on the men in service, of the needs and problems of servicemen's wives in seeking maternity and infant care, of the professional responsibilities and problems of physicians, nurses, hospitals and others rendering care, and of the practical experience of the state and local health agencies in administering the program.

The active cooperation of all who participate in the EMIC program is necessary to carry the program forward successfully through the war period and is earnestly sought by federal and state agencies charged with the administration of the program and by those concerned with the contribution that it can make to the morale of the enlisted men. The thousands of wives and infants that are now being given care daily is evidence of the great number of physicians, nurses and hospitals that are participating with the state and local health agencies in the program and so contributing to the war effort. The patriotic spirit with which service is being rendered is widely appreciated and, not least of all, by the wives of the enlisted men and by the servicemen themselves.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary.

GLOBIN INSULIN WITH ZINC.—"Globin insulin (with zinc) is a preparation, in a hydrochloric acid medium, of insulin modified by the addition of globin (derived from the hemoglobin of beef blood) and zinc chloride. The quantity of insulin used is such that each cubic centimeter of the finished preparation contains 80 U. S. P. units of insulin. The quantity of globin used (calculated as 6.0 times its nitrogen content) is not less than 3.6 mg. and not more than 4.0 mg. for each 100 U. S. P. units of insulin used. The preparation also contains, for each 100 U. S. P. units of insulin used, not less than 0.25 mg. and not more than 1.50 mg. total nitrogen. The pH of the finished preparation is not less than 3.4 and not more than 3.8. If necessary, either hydrochloric acid or sodium hydroxide may be added to obtain the required pH . The finished preparation also contains not less than 0.15 per cent and not more than 0.20 per cent (W/V) cresol-U. S. P., or not less than 0.20 per cent and not more than 0.26 per cent (W/V) phenol-U. S. P. The preparation is sterile."—Regulations promulgated Aug. 24, 1943 by the Administrator, Federal Security Agency: Certification of Batches of Drugs Composed Wholly or Partially of Insulin [8 Fed. Reg. 11837 (Aug. 27, 1943)].

Standards for Globin Insulin with Zinc and the Globin used in its preparation are set forth in the regulations cited.

Actions and Uses.—The effects of globin insulin with zinc are essentially the same as those of insulin (which see) except that the action is intermediate between that following regular insulin and protamine zinc insulin. The period of greatest effect extends from the eighth to the sixteenth hour after injection, almost disappearing at the end of twenty-four hours. This agent may be used for the treatment of diabetic patients in whom regulation of diet alone is incapable of providing adequate control and may be used in some patients to replace, wholly or partly, ordinary insulin. It is claimed to be indicated for those patients who require more than one daily injection of unmodified insulin and for those who cannot be controlled by other forms of insulin or who exhibit a sensitivity to protamine. It is said also to produce fewer local reactions on injection. It is not recommended for the treatment of diabetic coma and should never be administered intravenously. Globin insulin with zinc is quite stable but nevertheless bears on the label an expiration date for usage.

Dosage.—The general principles underlying the administration of this form of insulin are the same as those governing the use of unmodified insulin. It must be administered only by deep subcutaneous injection, not intramuscularly or intravenously. The daily dose required must be determined by a study of the patient. However, a starting dose may be about two thirds to three fourths of the total daily dose of regular insulin. This may be increased slowly as needed. If the patient has been receiving protamine zinc insulin, the globin insulin dosage on the first day should not exceed one-half the total dose of all insulin (regular, protamine zinc) received on the previous day. On the next day the dose may be increased to two thirds of the previous total insulin dosage and then slowly adjusted as required.

BURROUGHS WELLCOME & CO., INC., NEW YORK

Globin Insulin with Zinc: 10 cc. rubber capped vials.

U. S. Patent 2,161,198 (June 6, 1939; expires 1956).

SOLUTION OF EPINEPHRINE HYDROCHLORIDE 1:100 (See New and Nonofficial Remedies, 1943, p. 267).

The following product has been accepted:

CHEPLIN BIOLOGICAL LABORATORIES, INC., SYRACUSE, N. Y.

Solution Epinephrine Hydrochloride 1:100: 5 cc. Contains epinephrine 0.01 Gm., chlorobutanol 0.005 Gm. and sodium bisulfite 0.0001 Gm. as preservative in isotonic solution of sodium chloride.

HOSPITAL SERVICE IN THE UNITED STATES

TWENTY-THIRD ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

TABLE OF CONTENTS

HOSPITAL DATA, STATISTICAL TABLES AND TEXT	PAGES 839-850
INTERNSHIPS AND RESIDENCIES	PAGES 851-854
LIST OF REGISTERED HOSPITALS	PAGES 855-915
APPROVED SCHOOLS FOR OCCUPATIONAL THERAPISTS, PHYSICAL THERAPY TECHNICIANS, CLINICAL LABORATORY TECHNICIANS AND MEDICAL RECORD LIBRARIANS	PAGES 916-922
SCHOOLS FOR X-RAY TECHNICIANS	PAGE 916

The report for 1943 represents the Twenty-Third Annual Census of Hospitals by the Council on Medical Education and Hospitals of the American Medical Association. Included in this survey are 6,655 registered hospitals with a combined capacity of 1,649,254 beds and 77,134 bassinets. Their admissions reached a total of 15,374,698 during the year, the births a total of 1,924,591 and the average daily census 1,257,124. These figures when compared with previous reports give a clear indication of the enormous expansion that has taken place in the hospital field incident to wartime needs.

beds, an increase of 255,735 since 1942. The hospitals operating under state, county and city-county control showed an increase of 5,996 beds, whereas the church related and other nonprofit hospitals gained 6,416. A decrease in capacity occurred in the following groups: municipal hospitals 1,373 beds, proprietary hospitals 1,347.

The number of admissions in the registered hospitals set an all time record of 15,374,698, including neither newborn infants nor outpatients. This is an increase of 2,829,088, or 22.5 per cent, over the previous twelve months period. Most of this gain occurred in the

SUMMARY OF HOSPITAL DATA

	Number	Beds	Bassinets	Patients Admitted in 1943
1. Registered hospitals and sanatoriums approved for internships, residencies and fellowships	1,164	632,719	34,891	7,007,723
2. Other registered hospitals, sanatoriums and related institutions	5,491	1,016,535	42,243	8,366,975
Total registered	6,655	1,649,254	77,134	15,374,698

* As of Dec 31, 1943

In the last year the number of hospitals in the United States showed a net increase of 310. As one would expect, the largest gain occurred in the federal group, which now consists of 827 hospitals as compared with 474 in 1942. The other governmental groups gained 7 hospitals and the nonprofit organizations 30. The number of proprietary hospitals, however, was reduced by 80.

From 1909 to 1940 inclusive the average annual increase in hospital beds was approximately 26,000. The year 1941 showed an increase of 98,136 beds, while the next year added 59,446. There are now 265,427 more beds and 5,686 more bassinets than were reported in 1942. This recent growth is the equivalent of a new 727 bed hospital for each day of the year.

The expansion of bed capacity is almost entirely related to federal hospitals, which now have 476,673

federal group, which admitted 2,356,885 more patients in 1943 than in 1942. The general hospitals, it should be noted, had 14,454,638 admissions, or 94 per cent of all patients admitted to the registered hospitals, in 1943. One person every two seconds was the rate at which patients entered hospitals in the United States last year. In the same annual period 11.6 per cent of the entire population (1940 U. S. census) received inpatient hospital care.

The daily patient load or average census for all hospitals was 1,257,124 exclusive of newborn infants. This represents a total of 458,850,260 patient days of hospital service in 1943, an increase of 47,850,040 over the 1942 period. Comparative data for 1941, 1942 and 1943 showing the percentage of beds occupied in the various groups of registered hospitals, as well as the average length of stay per patient in the general hospitals, will be found in a subsequent section of this report.

Hospital births totaled 1,924,591 as compared with 1,670,599 in 1942 and 708,889 in 1931. In 1943, therefore, the hospital birth rate may be represented as one live baby every 16.3 seconds.

Schools of nursing education accredited by state boards of nurse examiners number 1,411. These, however, do not include training schools classified as tentatively approved. The student enrolment was reported as 110,222. In 1942 there were 1,439 accredited schools with 98,166 student nurses in training.

A new feature introduced in the present report is a study of hospital facilities for contagious diseases. This survey, which will be discussed at greater length later in the article, reveals that 1,649 hospitals provide 39,282 beds for this purpose. These facilities are in addition to 8,313 beds available in 55 isolation hospitals.

Special attention is called to tables 1 and 2, which give detailed information regarding hospitals in each state, bed capacity, number of bassinets, admissions and average daily census classified by control and type of service respectively. Each table, it should be noted, contains a further summary of the corresponding reports of the previous fifteen years.

Summary of Growth of Hospitals, 1909 to 1943

Year	Federal Hospitals		State Hospitals		All Other Hospitals		Total	
	Num-ber	Capac-ity	Num-ber	Capac-ity	Num-ber	Capac-ity	Num-ber	Capac-ity

Reference should also be made to the section on technical schools, which describes the work of the Council in relation to the approval and listing of schools for occupational therapy technicians, physical therapy technicians, clinical laboratory technicians, x-ray technicians and medical record librarians.

ACKNOWLEDGMENT

Special acknowledgment and appreciation is extended to the Surgeons General of the Army, Navy and Public Health Service, the great numbers of hospital administrators, assistants, chiefs and members of staffs, directors of technical schools, and other officials and personnel who have given their full cooperation in supplying the vast amount of information that has made possible the preparation of statistical data and lists as published in this issue.

When it is realized that reports were received from nearly 99 per cent of all registered hospitals, the extent of this cooperation and support becomes readily apparent.

It is especially gratifying that even under present conditions most hospitals were able to respond promptly and with complete information as required for the preparation of hospital lists and statistical reports.

METHOD AND SCOPE OF SURVEY

Four years ago the American Medical Association and the American College of Surgeons established a cooperative plan whereby the annual hospital questionnaires of the two organizations were combined into a single form. This method, which serves to unify reports and eliminate duplication of effort, has been welcomed by hospital administrators everywhere. To the hospitals registered by the Council and approved by the American College of Surgeons the annual census blanks are furnished in triplicate so that one copy can be returned to each organization while the hospital itself retains a copy for its own files. A similar blank is forwarded in duplicate to all other registered hospitals with the request that one copy be retained by the hospital while the other is returned directly to the American Medical Association. When these reports are received they are checked for completeness and accuracy, and follow-up studies are made if necessary to obtain full information as required for tabulation purposes and the preparation of the annual hospital list. Later the information is transferred to permanent file cards, from which the tabulations and lists are subsequently prepared.

It has been customary for many years for the hospitals approved for intern and residency training to supply their reports on an annual basis covering the calendar year immediately preceding the publication of the March Hospital Number. The other hospitals as a rule report earlier, usually for the twelve months period ended September 30. The need for a uniform census period has been recognized, and if possible this procedure will be established in connection with the next annual survey. It is hoped that the blanks for the intern and residency hospitals can be forwarded at an earlier date so that these institutions may have more time in which to prepare their reports.

While the American Medical Association and the American College of Surgeons cooperate in many activities relating to hospital standardization and service, each organization naturally maintains its own standards for approval, its own inspection service and lists of approved hospitals. In this connection it may be well to clarify some of the terms that are commonly employed in relation to hospital standardization programs. Registration is a basic recognition extended by the American Medical Association to hospitals and related institutions in accordance with the requirements described in the Essentials of a Registered Hospital as officially adopted by the House of Delegates of the American Medical Association in 1928 and revised in 1939. Registration is also concerned with the listing of hospitals in the Annual Hospital Number of THE JOURNAL and in the American Medical Directory. It should be noted that registration is a prerequisite for internship and residency approval.

Approval of hospitals by the Council means specific endorsement of a hospital's educational service in relation to intern or residency training. Recognition of this type is extended in accordance with the requirements outlined in the Essentials of an Approved Internship or the Essentials of Approved Residencies and Fellowships.

The term approved, as used by the American College of Surgeons, may be applied to those registered hospitals that meet the minimum standards of the College.

In the list of registered hospitals the approval of the Council for intern training is shown by a star (*), while approval of residencies in specialties is designated by a plus (+) sign. Approval by the American College of Surgeons is shown by the delta (Δ) and approval by state boards of nurse examiners by the diamond (\diamond) symbol.

In the survey of 1943 the annual census blanks were forwarded to 6,655 registered hospitals, including 2,678 approved by the American College of Surgeons. The Army, the Navy and the Public Health Service and other federal hospitals in the United States are also represented with exceptionally complete information in all groups. These reports are included in the various tabulations that appear in the present Hospital Number. Many of the new federal hospitals, however, are not shown in the published list and therefore any totals obtained from the list directly may vary from the totals that appear in tables 1 and 2.

Annual census blanks were also forwarded to 130 registered hospitals in Alaska, Canal Zone, Hawaii, Puerto Rico and Virgin Islands. These institutions are not included in the tabular data but are fully represented in the list of hospitals and sanatoriums.

During the last year 456 new institutions were admitted to the Hospital Register, whereas 146 were closed or transferred to the unclassified file. At present there are seventy-six applications pending in relation to hospital registration. There is a group of 523 hospitals which, according to information received, do not maintain a service in accordance with the requirements outlined in the general standards of the Council. These hospitals have only 15,215 beds, or less than 1 per cent of the total capacity of all hospitals. Certain other facilities are also omitted from the Register, namely clinics, emergency stations, offices, and so on, where bed care may be available as occasions demand. Many of these unclassified units constitute valuable auxiliary facilities in a community, even though their capacity may be limited to only a few beds.

Hospitals seeking registration should apply to the Council on Medical Education and Hospitals, American Medical Association, 535 North Dearborn Street, Chicago 10.

GOVERNMENTAL HOSPITALS

The classification of governmental hospitals includes hospitals operated by the various branches of the federal government, and those under state, county, municipal and city-county ownership and control. The most significant change in this group since 1942 is the large increase in federal hospital service in relation to war-time needs. The number of federal hospitals, for example, increased from 474 to 827, the admissions from 1,675,722 to 4,032,607 and the average daily census from 147,094 to 268,746.

Reference to table 1 will show that there have been relatively few changes in the state, county, city and city-county hospitals. They remained practically stationary in numbers, having gained only 6 hospitals in the county classification and 1 in the state group. All showed slight increases in bed capacity except the municipal hospitals, which decreased from 79,252 to 77,879 beds. In view of the improved economic conditions it could be expected that a reduction in hospital admissions would occur in these institutions. The state hospitals showed a decrease of 58,223 patients, the county hospitals of 24,684 and the municipal hospitals of 57,059. The city-county hospitals, however, reported

an increase of 36,233 admissions. Although fewer admissions were recorded, it should be noted that the average daily census increased in all groups except the hospitals under city control.

The governmental hospitals as a group increased from 1,924 to 2,284 in the last year, the beds from 1,015,781 to 1,276,139, admissions from 4,009,675 to 6,262,827 and the average census from 858,638 to 983,732. These

hospitals have 77 per cent of the total bed capacity; they received 40 per cent of the hospital admissions reported last year.

NONGOVERNMENTAL HOSPITALS

The nongovernmental hospitals may be divided into two general groups, the nonprofit organizations shown in table 1, section B, and the proprietary hospitals, included in section C of the same table. The nonprofit organizations comprise the church related hospitals and other nonprofit associations, while the proprietary group contains individual and partnership hospitals and corporations unrestricted as to profit.

The nonprofit group consisting of 2,956 hospitals showed a slight increase in beds, bassinets and average daily census. There was a substantial increase in the number of admissions, however, from 7,463,648 to 7,959,670. While this gain was shared by both the church related hospitals and the other nonprofit associations, the growth was somewhat greater in the church group.

Hospitals which discontinued their service were small and apparently had difficulty in securing sufficient personnel. In some instances the closing of individually owned hospitals became necessary when the physician in charge left to enter military service. The number of hospitals in this classification is now 1,415. Their bed capacity decreased from 51,755 to 50,408, but the bassinets increased by 353. Admissions increased from

TABLE 1—HOSPITAL FACILITIES BY STATES AND BY CONTROL:

It should be noted that the church related hospitals, 1,004 in number, have 130,488 beds, 3,503,396 annual admissions and an average daily census of 101.150. The other nonprofit associations comprising 1,952 hospitals report 192,219 beds, 4,456,274 admissions and 140.095 average census.

In the proprietary group there has been a net loss of 80 hospitals since the report of 1942. Many of the

1,072,287 to 1,152,201 and the average census from 31.236 to 32.147. The gain in number of admissions was more

These institutions, which number 4,371, have 23 per cent of the total bed capacity in all registered hospitals. They received approximately 60 per cent of the hospital admissions in 1943.

HOSPITALS ACCORDING TO TYPES OF SERVICE

The registered hospitals shown in table 2 have been divided into twelve groups in accordance with the type

bined capacity of 1,649,254 beds, 77,134 bassinets, 15,374,698 annual admissions and 1,257,124 average daily census.

The general hospitals constitute by far the largest group, as evidenced by the report of 850,576 beds, 72,839 bassinets, 14,454,638 admissions and an average census of 529,340. Their bed capacity increased by 256,316 last year, the admissions by 2,820,350 and the

last year and from 1,632,368 admissions to 3,984,895. Significantly, the downward trend continues in the tuberculosis group, which had 91,674 admissions last year as compared with 101,526 in 1942. Relatively few changes were noted in other classifications, however, but reference should be made to table 2, in which comparative data are available in relation to previous reports.

PERCENTAGE OF BEDS OCCUPIED

Comparative reports for 1941, 1942 and 1943 are included in the table showing occupancy rates in hospitals classified by control and according to type of service. It may be noted first of all that the average bed occupancy for all hospitals was 76.2 per cent in 1943 as compared with 81.4 per cent in 1942. This reduction in the face of a greatly increased admission rate may be accounted for in part by a shorter length of stay, but under present conditions it is more likely

that the rapid expansion of general hospital facilities in the federal group is the principal factor involved.

In support of this view may be cited the pronounced decrease in federal occupancy rates from 66.6 to 56.4 per cent in the last year and a similar reduction in the general hospital classification from 68.2 per cent to 62.2. Many of the new hospitals have been established in relation to future needs, and therefore the occupancy rate has not always kept pace with the number of beds available. In this connection it should be noted that several of the newly established hospitals have been included in this report with only the bed capacity available for tabulation purposes.

The fact that city and city-county hospitals showed a continued reduction in bed occupancy is in keeping with the improved economic conditions of the country. In the nongovernmental group the church related hospitals showed an increase over the previous year, while the other nonprofit hospitals had an average occupancy of 72.9 per cent as compared with 74.5 in 1942. In tuberculosis hospitals there has been a further decrease in bed occupancy, while in the nervous and mental institutions an increase may be noted. The occupancy in industrial hospitals has increased from 55.5 per cent in 1942 to 59.5 per cent in 1943. As would be expected, the lowest occupancy rate, 38.7 per cent, occurs in iso-

lation hospitals, where bed reserves are usually maintained to meet seasonal demands.

As regards the average length of stay in general hospitals, it may be noted that a reduction of two days occurred in the federal group, two days in state hospitals and one day in the city-county institutions. In other

groups the average length of stay was identical with the 1942 report. The accompanying table shows the following length of stay in general hospitals: governmental nineteen days, all nonprofit associations ten days, proprietary hospitals eight days. This indicates an average of thirteen days for the general hospitals as a group.

BIRTHS IN HOSPITALS

Use of hospital facilities for maternity care continues to increase, as evidenced by the report of 1,924,591 hospital births in 1943 as compared with 1,670,599 in 1942 and 621,896 in 1929. The governmental hos-

Total births in all hospitals.....	621,896	1,424,299	1,779,196	1,924,591

pitals reported 273,691 births last year, church hospitals 656,367, other nonprofit associations 795,184 and the proprietary hospitals 199,349. More than 96 per cent of the births reported in 1943 were in general hospitals, while 3.4 per cent occurred in maternity hospitals. It is of further interest to note that the nongovernmental hospitals had 85 per cent of the births, the governmental group 15 per cent. Attention is called to the table

showing births in hospitals classified according to control and type of service. Comparative data are given for the years 1929, 1941, 1942 and 1943. The distribution of bassinets in the various types of hospitals is given in tables 1 and 2.

ADMINISTRATIVE PERSONNEL

In the present survey information was again obtained regarding the administrative supervision of hospitals by physicians, nurses or other hospital superintendents. From reports available on 6,655 registered hospitals it has been ascertained that physicians serve as administrators or superintendents in 2,654 hospitals, registered

number of orderlies, however, increased by 5,283 and the personnel has been further augmented by 34,801 nurses' aides and 13,167 additional graduates not listed in previous reports. Reference should be made to the table giving further information on administrative and nursing personnel and schools of nursing.

SCHOOLS OF NURSING EDUCATION

Schools of nursing education accredited by the respective state boards of nurse examiners now total 1,411 as compared with 1,439 in 1942. Schools that have been classified as tentatively approved are not included in this report. For many years there has been a decrease

nurses in 2,258 and other persons in 1,743. There has been a decrease of 9 nurse superintendents since the report of 1942, while the classification of physician superintendents shows a gain of 374. This corresponds closely to the increase of 353 hospitals noted in the federal group.

NURSING PERSONNEL

Reports received in the 1943 survey show that the registered hospitals employ 113,424 graduate nurses on nursing service, 13,167 other graduate nurses, 17,309 practical nurses, 34,801 nurses' aides, 92,427 attendants and 31,140 orderlies. When compared with the 1942 report it is apparent that the number of graduate nurses employed for nursing service has decreased by 6,690, practical nurses by 4,852 and attendants by 1,706. The

in the number of schools of nursing, yet the number of students enrolled has steadily increased. The present report gives a total of 110,222 student nurses, an increase of 12,056 over 1942.

In the listing of accredited schools in the Hospital Register, two symbols are employed to differentiate between institutions conducting schools and those which supply training on an affiliated basis. The circular symbol (○) refers to hospitals which provide acceptable supplementary training in a limited field as, for example, pediatrics, psychiatry, tuberculosis or contagious diseases. The diamond symbol (◊), however, is applied to accredited schools of nursing operated by hospitals individually or under joint hospital and college or university sponsorship.

TECHNICAL PERSONNEL IN HOSPITALS

Information on technical personnel was first published in *THE JOURNAL*, March 27, 1937. More complete data, however, were obtained in 1941, when additional groups were included to supply a full report on laboratory, x-ray, physical therapy and occupational therapy technicians, dietitians, pharmacists, medical record librarians, other librarians, medical stenographers, dental hygienists and social service workers. Data were presented in *THE JOURNAL*, March 28, 1942, showing both

1,883 full time and 351 part time technicians, while dental hygienists total 1,574 and 524 respectively. Social service workers include 3,996 on full time and 3,147 on part time, nurse anesthetists 3,609 and 1,242.

Reference to the accompanying table on technical personnel will show that there has been a definite increase in most of these groups in the last year. Since many of these changes are related to the expansion of federal hospital services, comparative totals have been included in the tabular data.

full time and part time workers in all of these classifications. In 1942 additional information was included regarding nurse anesthetists. In connection with the present annual census, the registered hospitals reported 13,349 laboratory technicians on full time duty and 2,073 on part time, 7,834 x-ray technicians full time and 1,783 part time and 6,482 dietitians full time and 609 part time. Other groups classified as full time and part time respectively show the following numbers: physical therapists 2,905 and 719, pharmacists 3,563 and 605, medical record librarians 4,155 and 1,191, other librarians 1,039 and 523, and medical stenographers 8,816 and 1,202. In occupational therapy there are

A further report on the work of the Council on Medical Education and Hospitals with reference to laboratory technicians, occupational therapists, physical therapists, medical record librarians and lists of approved schools will be found in later pages of this issue. There is also an announcement regarding the activities of the Council relative to the formation of standards and the preparation of lists of acceptable schools for x-ray technicians.

FACILITIES FOR CONTAGIOUS DISEASES

Information regarding isolation hospitals has been included in the surveys of the Council for many years. These reports, as summarized in table 2, show that the

number of hospitals devoted to the care and treatment of contagious diseases has decreased from 98 in 1927 to 55 at the present time. During this period there has also been a reduction in bed capacity from 8,895 to 8,313. The number of beds reported in the last survey, however, shows an increase of 2,034 in comparison with

the year 1942. Admissions have varied from 30,279 in 1939 to 49,570 in 1943, the latter representing a gain of 11,634 over the previous twelve months period. As regards occupancy rates it can be shown that an average of 36.1 per cent of the beds in these hospitals were occupied in 1929, 41.8 per cent in 1936 and 38.7 per cent in 1943. The average daily census last year was 3,219 and the average length of stay 23.7 days.

It is recognized, of course, that isolation hospitals do not furnish all the facilities required for the segregation and care of contagious diseases throughout the country.

Many other hospitals maintain units for isolation care or the temporary hospitalization of patients awaiting transfer to other contagious disease departments. To ascertain the full scope of this service, therefore, all the hospitals were asked in the last annual survey to indicate whether isolation facilities are furnished for contagious diseases and, if so, how many beds are avail-

able. Tuberculosis facilities were not included in this study. Reports were received from nearly 99 per cent of the 6,655 hospitals registered by the American Medical Association. These indicate that 1,649 hospitals exclusive of the isolation hospitals already described can supply 39,282 beds for contagious disease care. Included in this number are 156 hospitals which reported available facilities but did not specify the number of beds.

Five hundred and seventy-nine federal hospitals report 27,499 beds for this type of service, whereas 178 state hospitals have 3,095 beds, 110 county hospitals 1,411, 81 municipal hospitals 2,916 and 21 city-county hospitals 398. In the nongovernmental group it was found that 181 church related hospitals have 1,098 beds, 338 other nonprofit hospitals 2,436 and 161 proprietary hospitals 429.

As regards general hospitals it can be shown that 1,336 supply 34,345 beds for the isolation and care of contagious diseases. These general hospital facilities may be subdivided as follows: 541 federal hospitals 27,131 beds, 202 state, county and city hospitals 3,960 beds and 593 nongovernmental hospitals 3,254 beds.

Reference should be made to the tables showing contagious disease departments classified by states, control and type of service.

DISEASE NOMENCLATURE

The new edition of the Standard Nomenclature of Disease was published by the American Medical Association in June 1942. The Standard Nomenclature of Operations, a new publication, is incorporated in the same volume.

In 1942, 1,014 hospitals stated that they were using the Standard Nomenclature. During 1943, 1,660 hospitals reported the use of the Standard Nomenclature or specialized classification based on it. Approximately 1,000 hospitals employ Ponton's Alphabetical, Massachusetts General Hospital or the Bellevue Hospital classification. Other systems were reported by 240 civilian hospitals. The Standard Nomenclature is now employed in all United States Public Health Service hospitals.

According to the returns from the annual questionnaire at least 600 additional hospitals installed the Standard Nomenclature between 1942 and 1943. Hospitals planning to establish a modern disease classification should consider the adoption of a nomenclature that is suitable for universal use. The Standard Nomenclature of Disease has been officially endorsed by the American Medical Association, the American College of Surgeons, the American Hospital Association and several other medical and surgical societies.

INTERNSHIPS AND RESIDENCIES

On Jan. 1, 1944, when the 9-9-9 program of the Procurement and Assignment Service was inaugurated, there were 715 civilian hospitals approved for internships and 659 for residency training. The total number of approved hospitals, however, was 1,054, since 320 were accredited in both classifications. The federal hospitals approved by the Council for intern and residency training are not included in the present study.

Reports received at the beginning of the year showed that the approved hospitals had 5,170 interns on duty, 1,452 assistant residents and 2,064 resident physicians. These figures, it should be noted, are considerably lower than those reported in January 1943, when 5,567 interns were employed, 1,210 assistant residents, 2,633 resident physicians and 609 fellows. The present distribution of interns and residents, by states, is shown in the accompanying table.

A separate article describing the present status of the 9-9-9 program is included in this report. On purely educational grounds it would be impossible to defend a nine month internship, which must be regarded as a wartime educational casualty. Reluctantly, and only after careful consideration of the advantages and disadvantages and weighing the possible alternatives, the Council has recognized the so-called 9-9-9 plan as the best available under present wartime conditions.

The plan conserves medical manpower for both military and civilian use. Each year approximately 7,000 men graduate from medical schools under the accelerated program. Under the old plan, three months of their internship would overlap with the internships of the next class. The quality of instruction in the overlapping period was often inferior, adding considerably less than the equivalent of three months' time to the nine month overlapping period.

The 9-9-9 program assures the deferment of assistant residents and residents, even though the period of additional training is less than the three or more years generally considered desirable, and readily attainable in peacetime. It was the only method of deferment of commissioned officers as assistant residents and residents on which agreement could be reached. If a one year internship was to be continued, hospitals would be forced to operate without any commissioned officers deferred as residents. It is better to have one third of the intern group continue for nine months as assistant residents and one sixth of the group for a second nine months as residents than to have no deferments for hospital service after the first year of internships. The latter was apparently the only alternative and was considered to be less desirable than the 9-9-9 program.

TYPES OF INTERNSHIPS

The internship has long been considered an essential preparation for general practice and a prerequisite for subsequent specialty training. It now holds a similar relationship to the needs of the military service and should therefore be organized in such a manner that interns will receive wide experience in the major divisions of medicine and a thorough training in modern medical technics. To accomplish this purpose most hospitals are offering a rotating type of service, as evidenced by recent reports. These indicate that 673, or 94 per cent, of the approved internships are of the rotating type, while only 23, or 3 per cent, are mixed and 19, or 2 per cent, straight. Ten hospitals have

combined services, such as rotating and straight or straight and mixed.

In relation to individual internships, it can be shown that 4,551 interns, or 88 per cent of the total number, are now serving on a rotating basis and 152, or 3 per cent, are in the mixed group, while 467, or 9 per cent, have straight assignments. In 1942 the corresponding figures were 86.2, 3.2 and 10.5 respectively.

INTERNSHIP VACANCIES

The inauguration of the 9-9-9 program in January required many hospitals and house officers to make rapid adjustments in relation to quota allocations. To assist in this matter the Council published weekly lists

in THE JOURNAL giving names of hospitals in need of interns and resident physicians. Copies of these lists were furnished regularly to all medical schools and to individual applicants. Since November 12 approximately 475 hospitals have been listed with essential data regarding location, bed capacity, annual admissions, name of superintendent and number of interns and residents required. This procedure, which is still in use, has been effective in meeting the needs of many institutions and applicants. The Council will be glad to be of further assistance to hospitals and interns whenever difficulties are experienced in obtaining house staff appointments.

Under the present accelerated program of medical education there may be considerable difficulty in adjusting hospital internships to the various periods of graduation. By careful analysis of this problem in relation to

future graduating classes it will usually be possible to stagger appointments in such a way as to insure reasonable continuity of intern service from year to year. The accompanying list of medical schools showing dates of graduation for 1944 and 1945 should prove helpful to hospitals in the selection of future interns.

GRADUATES OF LATIN AMERICAN SCHOOLS

The Council has stated that hospitals approved for internships and residencies may accept graduates of Latin American schools as interns or resident physi-

cians. The responsibility for evaluating credentials, however, must necessarily rest with the hospitals involved, since the American Medical Association has not investigated and classified medical schools outside the United States and Canada. In this connection it will be of interest to know that the Directing Board of the

Procurement and Assignment Service has decided that graduates of Latin American medical schools currently serving as interns or residents will not be counted in the hospital quotas.

It was felt that most Latin American doctors who accepted internships or residencies were in fact postgraduate fellows attached to United States hospitals. In some instances language difficulties precluded their rendering as much medical care to hospital patients as native born and United States trained house officers. If Latin American physicians were to be counted in hospital quotas, there would be some hesitancy in accepting them in lieu of native born United States medical graduates.

Since it is highly desirable to have Latin American physicians seek postgraduate medical training in the United States, dropping them from hospital quotas would encourage hospital superintendents to accept them as interns and residents and thus facilitate their securing additional training in this country.

COMPENSATION FOR INTERNS

It is well known that medical graduates seeking hospital appointment are primarily interested in educational returns. Financial remuneration, therefore, has generally been regarded as a minor factor in the selection of an internship. In the Hospital Number of 1938 it was shown that 84.4 per cent of the interns served without salary or received \$25 a month or less. When similar reports were analyzed in 1940 it was found that 153 hospitals offered no salaries to the intern staff, 170 paid less than \$25 a month, 311 offered \$25 to \$49 and 41 listed \$50 to \$74, while only 2 paid as high as \$75. Sixty-five of these hospitals gave a bonus in addition to the regular monthly stipend.

The competition for interns in recent years has caused a considerable increase in salary schedules in many institutions. Thus it is shown in the reports of 1943 that only 85 approved internship hospitals are now operating without salaries for interns and 68 offer less than \$25 a month, while 158 are in the group of \$25 to \$49. In 1940 only 43 hospitals had salaries beyond this point, whereas at present 199 offer \$50 to \$74, 89 offer \$75 to \$99 and 77 offer \$100 or more. Nine hospitals grant compensation solely in the form of a bonus, but in addition there are 75 institutions listed whose stipends are supplemented by a monthly or annual bonus. In this connection it is of interest to note that in the group of hospitals paying \$100 or more one offers \$175 a month, one \$165, four \$150, one \$140, seven \$125, one \$120 and the rest \$100.

On further analysis it can be shown that 68 per cent of the present interns receive no salary or less than \$50 a month, 24 per cent are in the \$50 to \$99 group, 6 per cent receive \$100 or more and 2 per cent obtain bonus payment without regular salary allowance.

NECROPSY PERFORMANCE

The incidence of necropsy performance has long been considered a reliable index of the quality of educational service in hospitals. From the standpoint of intern training interest is centered not only in the ratio of post-mortem studies but also in the volume of pathologic material available for house staff instruction. Both of these factors are included in the standards of the Council, which specify that hospitals undertaking the respon-

sibility of training interns should provide a minimum necropsy rate of 15 per cent and at least thirty-six postmortem examinations a year. In computing the necropsy ratio, all hospital deaths are considered with the exception of stillbirths and such coroners' cases as are not available for teaching purposes. Other factors involved in the computation of necropsy percentages were described in *THE JOURNAL*, March 11, 1939, page 924.

In 1943 the hospitals approved for intern training reported a total of 229,438 deaths exclusive of stillbirths and cases released to legal authorities. The number of necropsies was 71,808, indicating an average ratio of 31.7 per cent as compared with 36.5 per cent in the previous year. From 1938 to 1941 the corresponding rates were 37.6, 37.8, 38.9 and 38.97 respectively. For comparative purposes it is of interest to note that 74,879 postmortem examinations were performed in 1942, 82,587 in 1941 and 81,849 in 1940. In this connection, however, it should be mentioned that the data for the last two years do not include the reports of federal hospitals approved for intern training.

Apparently the loss of medical personnel and the reduction in house staffs have seriously impaired the ability of many hospitals to maintain a satisfactory necropsy program. This is illustrated in the table on necropsy performance, which shows continual advancement in the peacetime period of 1926 to 1941, whereas the last two years evince a considerable reversal of the higher percentage levels and a significant increase in the number of hospitals with rates of less than 15 per cent. One hundred hospitals were unable to fulfil the 15 per cent requirement in 1943, as compared with 8 in 1940, 18 in 1941 and 43 in 1942. In relation to the numerical requirement, it may be noted that 168 hospitals failed to

Carolina 2, Tennessee 2, Texas 6, Virginia 1, Washington 4, West Virginia 4 and Wisconsin 2. These figures should be considered in relation to the number of hospitals approved for intern training in the respective states.

It is encouraging to note that 313 hospitals were able to obtain a ratio of 30 per cent or more in 1943, for this

indicates that even under wartime conditions it is possible to maintain the essential functions of an educational program. Other hospitals should likewise bend every effort in this direction, for with the reduction of internships to nine months it is particularly important that the quality of house staff instruction be preserved at such levels as will insure adequate preparation for civilian and military service.

Twenty-one hospitals have the highly commendable rate of 70 per cent or over, as shown in the accompanying list. Their accomplishment should serve as an inspiration and incentive to other hospitals in the educational field.

The intern and residency hospitals as a group reported 272,044 deaths and 83,311 necropsies, an average ratio of 30.67 per cent. In 1942 the rate was 35.2 on the basis of 249,383 deaths and 87,687 postmortem examinations.

achieve a minimum of thirty-six necropsies during the year. Eighty of these institutions were also deficient on a percentage basis.

The number of hospitals reporting necropsy rates below 15 per cent are distributed as follows: Florida 2, Georgia 4, Illinois 7, Indiana 3, Iowa 4, Kentucky 3, Maine 1, Maryland 1, Massachusetts 7, Michigan 3, Missouri 1, New Jersey 10, New York 9, North Carolina 1, Ohio 8, Oklahoma 2, Pennsylvania 13, South

POSTWAR GRADUATE MEDICAL EDUCATION

It is anticipated that thousands of physicians whose hospital training has been interrupted by the call to military service will be seeking advanced training after the war. The Council on Medical Education and Hospitals, therefore, has undertaken a study of postwar graduate educational facilities as one of its major responsibilities. It has recently completed a preliminary survey to determine all available and potential facilities for advanced training in connection with intern and residency hospitals, undergraduate and graduate medical schools, departments of health, state medical associations and other agencies interested in graduate and postgraduate medical education.

A report of the Council's studies was published in the Jan. 1, 1944 issue of *THE JOURNAL*. Reprints of this article were later distributed to the various agencies, organizations, institutions and committees concerned with postwar educational and medical problems. The report shows clearly that constructive planning is already under way and that institutions are anxious to cooperate to the full limit of their facilities in providing hospital residencies, basic medical science instruction and postgraduate courses as may be required by the returning medical officers.

There are indications that a large number of younger medical officers are desirous of postgraduate medical education after the war. In a recent sample study it was found that more than 80 per cent of medical graduates (1938 to 1943) expressed an opinion that they would like to qualify for certification by an American

Specialty Board. It is appreciated that there may be some shifting of point of view of these men with the progress of the war. However, the high percentage of voluntary expressions for continued specialized hospital training is significant in relation to possible future needs.

The present plan of wartime graduate medical meetings is serving a very useful course of instruction for all medical officers. Some of the older physicians have expressed a preference for a short refresher course of instruction of four to eight weeks for their postwar medical training. They have suggested that refresher courses be patterned after the present wartime graduate medical meetings. Courses are to be held in the large

medical centers and be an intensive clinical review of general and special subjects.

This study of postwar educational facilities will be continued so that the Council will be able, at the close of the war, to provide a complete printed list of all available educational opportunities. The Committee on Postwar Medical Service of the American Medical Association is now distributing questionnaires to Army, Navy and Public Health Service medical officers which will give further information regarding the educational desires of these men. With this information at hand, the Council will be able to proceed more effectively in its study of the required facilities for postwar graduate training.

PRESENT STATUS OF INTERNSHIP

Lieutenant Colonel Harold C. Lueth, M. C., U. S. Army

Liaison Officer, American Medical Association

The Procurement and Assignment Service adopted the 9-9-9 plan on Oct. 15, 1943. Briefly, the plan is a uniform system of nine months training as interns, a second nine month period as an assistant resident and a third nine month period as a resident. The Procurement and Assignment Service was confronted with providing sufficient numbers of recent medical graduates to the armed services for duty and at the same time assuring civilian hospitals of an adequate supply of house officers. To meet these objectives, state quotas of interns and residents were prepared for the civilian hospitals of the United States. The data shown in the 1940 Annual Report of Hospitals prepared by the Council on Medical Education and Hospitals were used as a basis. In general the quota was a proportionate ratio of the total number of interns and residents on duty at the hospitals as of March 15, 1940. Certain adjustments were made for hospitals with large teaching programs and hospitals with large increases in patient loads. There was a general increase of 14 per cent in hospital admissions in 1943 compared to 1940, so that a hospital had to have an increase of more than 14 per cent before it could claim additional house staff on the basis of an increased patient load.

Acceleration of the medical curriculum resulted in a large number of medical graduates who became available for hospital service every nine months. A nine month hospital internship and residency was the most efficient method of integrating the accelerated medical curriculum with hospital needs. It avoids the delays, overlapping and wastage of a one year hospital service. Objection has been raised to the nine month period of hospital service on the ground that it is not adequate for peacetime standards of medical education. The 9-9-9 plan was the most feasible method of deferment of commissioned officers as assistant residents and residents that could be approved by Surgeons General of the Army and Navy. If a one year internship was to be continued, hospitals would be forced to operate without any commissioned officers as residents. The 9-9-9 plan thus provides the most efficient use of recent medical graduates, assures young physicians the best hospital training that is possible under wartime conditions and permits the widest possible coverage of house officers to all hospitals. It should however be pointed out that hospitals requesting nine month deferments of intern and junior residents should make their

decision with reference to the personnel they desire as early as possible in order that the deferment request may be forwarded through the central office of the Procurement and Assignment Service to the Surgeon General of the Army and Navy at least sixty days prior to the date on which the intern or assistant resident would normally be called to active duty.

Some shifting of personnel and rearrangement of services was necessary during the conversion period. Many local changes aided in the success of the plan. State chairmen were empowered to change quotas between hospitals when not more than three house officers were involved. House officers were often called on to cover more than one service. In a hospital that formerly had eight surgical residents and two ear, nose and throat residents, for example, a reduction to six residents in surgery occurred under the 9-9-9 plan. Obviously some of the residents in surgery had to provide service for the ear, nose and throat department. In general most hospital superintendents handle such problems well.

Many hospitals had selected their intern and resident staffs on the traditional one year basis in advance of the advent of the 9-9-9 plan. There was some skepticism in regard to the likelihood of persuading recent graduates who had been accepted for hospital training at one hospital to accept an internship elsewhere. Through the cooperative efforts of the deans of medical schools, hospital superintendents, state and local chairmen, Procurement and Assignment Service, hospital staffs and the interns and residents involved, the conversion was accomplished with surprisingly little difficulty. A clearing house arrangement was formulated through the assistance of the Council on Medical Education and Hospitals. Hospitals with quota allotments and without interns and residents were published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. After the first few weeks of the transitional period there were very few hospitals entitled to interns and residents without such personnel. The initiation of the 9-9-9 plan called for a reduction of more than 8,100 approved internships of one to three years length and nearly 6,000 approved residencies of similar length to 6,000 internships and 4,200 residencies of nine months duration. The successful operation of the 9-9-9 plan reflects the earnest cooperation of all concerned and illustrates the willingness of American medicine to make those necessary sacrifices of a nation at war.

HOSPITALS REGISTERED BY THE AMERICAN MEDICAL ASSOCIATION

The following list contains the names of 6,655 hospitals, sanatoriums and related institutions that are located in the United States and 130 in Alaska, Canal Zone, Hawaii, Puerto Rico and Virgin Islands. The list for each state is presented in two groups: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include infirmaries, nursing homes and other institutions designed to give certain medical and nursing care in an ethical and acceptable manner, without giving a full hospital service.

Registration of hospitals is governed by the Essentials of a Registered Hospital, adopted by the House of Delegates in 1928 and revised in 1939.

Registration is a basic recognition, extended to all the hospitals and related institutions in the following list, concerning which we have no evidence of irregular or unsafe practices. Approval is designation of certain registered institutions by the Council on Medical Education and Hospitals for internships, residencies and fellowships; or by the American College of Surgeons as unconditionally meeting its minimum standards.

KEY TO SYMBOLS AND ABBREVIATIONS

* Approved for training interns by the Council on Medical Education and Hospitals. List with detailed information is sent on request.
† Approved for residencies or fellowships. List with detailed information is sent on request.

▲ Approved by American College of Surgeons as meeting unconditionally its minimum standards.
○ School of nursing accredited by state board of nurse examiners.
○ Affiliated for nurse training on state accredited basis.
† Figures for "average census" and "admissions" are exclusive of newborn infants.

The column headed "Type of Service" tells what diseases are treated in each institution:

Card	Cardiac	ENT	Eye, ear, nose and throat	Iso	Isolation	N&M	Nervous and mental
Chil	Children	Gen	General	Mat	Maternity	Orth	Orthopedic
Chr	Chronic	Incur	Incurable	MatCh	Maternity and children	SkCa	Skin and cancer
Conv	Convalescent and rest	Indus	Industrial	McDe	Mentally deficient	TB	Tuberculosis
Drug	Drug and alcoholic	Inst	Institutional	Ment	Mental	Ven	Veneral
Epil	Epileptic						

The column headed "Control" indicates control, or auspices under which the institution is conducted:

GOVERNMENTAL			NONPROFIT ORGANIZATIONS		PROPRIETARY	
Fed	Federal	State	Church	Indiv	Indiv	Individual
LA	Indian Affairs	City	NPAssn	Part	Part	Partnership
Army	United States Army	County		Corp	Corp	Corporation (unrestricted as to profit)
Navy	United States Navy	City-County				
USPHS	United States Public Health Service	CyCo				
Vet	Veterans Administration Facility					

The accompanying list omits additions to hospital facilities that may have been made by certain departments of the Federal Government since the publication of the issue of March 15, 1941.

Corrections were made in the list to the time of going to press. Totals of the list, therefore, may vary from totals in Tables 1 and 2 which were necessarily compiled earlier.

SCHOOLS FOR X-RAY TECHNICIANS

The American Registry of X-Ray Technicians, which is sponsored by the American College of Radiology, requested that the American Medical Association assume the responsibilities of approving schools for x-ray technicians. This request was embodied in a resolution presented to the House of Delegates of the American Medical Association during the 1943 session. Action on the resolution delegated the Council on Medical Education and Hospitals to establish standards of training and to inspect schools and publish lists of approved courses.

Selected schools have been visited and information has been obtained from others. Much valuable assistance has been furnished by the American Registry of

X-Ray Technicians and the American College of Radiology in correlating this information with desirable standards of training. In cooperation with the American Registry of X-Ray Technicians and the American College of Radiology the Council on Medical Education and Hospitals has prepared minimum essentials which will be presented to the House of Delegates at its next session in June 1944. These essentials will probably be published in one of the June or July issues of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. Reprints will be available at a later date. Graduate x-ray technicians desiring registration should communicate with the American Registry of X-Ray Technicians, 2909 Raleigh Avenue, Minneapolis 16.

SCHOOLS FOR MEDICAL RECORD LIBRARIANS

The American Association of Medical Record Librarians presented a formal resolution to the 1942 session of the House of Delegates of the American Medical Association requesting the latter to assume the responsibilities of approving schools for medical record librarians. Action on the resolution granted the Council on Medical Education and Hospitals authority to establish standards, inspect training programs and publish lists of approved schools. Minimum essentials were formulated with the assistance of the American Association of Medical Record Librarians after all existing schools were inspected. These essentials were officially accepted by the House of Delegates in 1943. The first list of approved schools was published in June 1943. Currently there are 10 schools on the approved list.

Graduates of the approved schools are eligible to take registration examinations and are qualified to assume the responsibilities of a record department. Organized instruction in most instances exceeds the minimum required in the essentials. Twenty-five of the 27 graduates last year had had considerably more than the minimum experience in the record room and related departments. All students obtained more than the required amount of organized instruction.

The maximum capacity of all approved schools is 90 students a year. This is considerably less than the 729 additional medical record librarians employed full time in United States hospitals during 1943. Unless additional schools are developed and sufficient students are trained properly, hospitals will be forced to rely on increasing numbers of inadequately qualified personnel in the record department.

Six of the 10 approved schools are affiliated with colleges or universities. Three training programs are completely coordinated with collegiate studies and are designed for high school graduates who desire a four year degree course. Under these conditions twelve months are devoted to supervised hospital instruction and experience. During this time students earn from 8 to 30 semester credits for the hospital instruction.

Special or short courses are organized in 6 schools for experienced medical record librarians who are preparing to take examinations for registration or who desire to become familiar with the Standard Nomenclature.

Correspondence regarding registration should be addressed to the Board of Registry of the American Association of Medical Record Librarians, St. Luke's Hospital, Milwaukee.

SCHOOLS FOR OCCUPATIONAL THERAPY TECHNICIANS

At the 1933 session of the House of Delegates of the American Medical Association a resolution was introduced that some plans be effected for the establishment of standards, ratings and inspections of training schools for occupational therapy technicians. This program was referred to the Council on Medical Education and Hospitals, and all of the 13 existing schools were surveyed. The Essentials of an Acceptable School of Occupational Therapy were ratified by the House of Delegates of the American Medical Association at the Atlantic City session in 1935, such standards to become effective on Jan. 1, 1939. A report of the Council on Medical Education and Hospitals to the House of Delegates in 1936 contained the names of 4 schools which had already met these standards. There are currently 13 schools on the approved list.

Six schools for occupational therapy technicians were approved last year. An equal number of schools have started classes and will be ready for consideration in the next year or two. Interest in creating new schools has resulted in the sudden expansion of occupational therapy departments in the hospitals maintained by the armed forces. Graduates of the approved schools are eligible for U. S. Civil Service appointments in Army hospitals.

In the calendar year of 1942, 146 students were graduated by the 7 approved schools. There were 162 graduates in 1943. Five of the 13 currently approved schools will have their first graduates during 1944.

Anticipated graduates for 1944 total 218 in the approved schools and 14 in the recently established schools. Emphasis has been placed on increasing the

student enrolment in regular and advanced standing courses. Also several of the schools have accelerated their training programs by offering three semesters each year. These factors might make it possible to graduate more than the anticipated number of 232 during 1944. However, the maximum capacity of all schools totals 553 for the senior year plus 172 for the short or advanced standing courses. Thus a maximum of 725 students could be trained next year by the approved schools and those new schools which will probably be considered during the year. It appears that enrolment equaling the present maximum capacity of all schools will be necessary to satisfy Army needs for the next two years. Requirements of civilian hospitals, Veterans Administration facilities, rehabilitation programs and others will create an extra demand. The total needs will greatly exceed the maximum capacity of all schools.

The long period which is necessary to train prospective graduates adequately in the arts, crafts, biologic sciences and medical subjects handicaps the efforts to produce large numbers of occupational therapy technicians in a short time. Advanced standing courses open to individuals who have had sufficient collegiate training in the arts and crafts require from sixteen to twenty-one months instruction and experience before these students are thoroughly qualified. Instruction is on the college level in all but one school, and the instruction there appears to be very similar to that found in many accredited colleges.

SCHOOLS FOR PHYSICAL THERAPY TECHNICIANS

The House of Delegates of the American Medical Association in 1934 requested that some plan be effected for the establishment of standards, ratings and inspections of schools for the training of physical therapy technicians. The Council on Medical Education and Hospitals assumed responsibility for this program and by 1936 had completed a survey of these schools. Certain minimum standards were formulated. These were presented to the House of Delegates of the American Medical Association and were ratified in May 1936. The first published list of 13 approved schools for physical therapy technicians appeared in THE JOURNAL in August 1936. At present there are 28 approved schools.

Six month emergency courses continue to be popular. The 17 schools approved for this type of training produced 235 physical therapy aides last year. After obtaining an additional six months of experience in army hospitals, these students are eligible for registration examinations. Individuals who are planning to work in civilian hospitals should not take the emergency course but should enroll in the regular course, which is presented in nine or more months of instruction. The 23 schools offering the regular course graduated 190 students in 1943. Emergency and regular programs trained 435 students, or an increase of only 9 over the previous year.

Army needs for properly trained physical therapy technicians or aides were much greater than the total graduates. Estimates of Army and Navy needs for the current year are over twice the present number of graduates. In fact the needs exceed not only the 719

anticipated graduates during 1944 but also the maximum capacity of both the regular and the emergency courses, or 816 students. Next year the Veterans Administration and rehabilitation programs will probably require equally large numbers of graduates. To meet these demands there must be more schools approved, and greater effort will be required to encourage more students to enroll.

Only four of the approved schools require more than the minimum entrance requirements of two years of college credit. Ten of the schools have courses arranged so the students can receive from 20 to 50 semester hours of credit toward a degree, while one four year program grants 131 credits. Tuition is not charged for seven of the emergency courses and three of the regular curriculums. A total of 220 graduates were produced by these ten courses. Other schools charge from \$72 to \$432 a year, but many of the higher tuitions are university fees. The mean tuition of all emergency courses remains at \$200, while the average has dropped to \$132. Tuition for the regular curriculum averages \$212, while the mean is \$200.

Universities, medical schools, colleges or hospitals having suitable facilities in physical therapy are urged to consider the establishment of acceptable programs in this field.

For further information regarding the approval of technical courses, communicate with the Council on Medical Education and Hospitals. Individuals desiring registration should write to the American Registry of Physical Therapy Technicians, 30 North Michigan Avenue, Chicago 2.

* Courses are so arranged that any of the entrance requirements will qualify students for training. a = Graduation from accredited school of nursing; b = Graduation from accredited school of physical education; c = Two years of college with science courses; d = Three years of college with science courses.

† For complete information regarding entrance to Army training schools write to Major Emma E. Vogel, Director of Physical Therapy Aides, Office of the Surgeon General, War Department, Washington, D. C.

1. Male students admitted.
2. High school graduates accepted for four-year course leading to A.B. degree; students admitted quarterly and tuition is \$143 per quarter.
3. High school graduates admitted to regular course.
4. Medical technology graduates with B.S. degree also admitted.
5. Non-residents charged additional fee.
6. Those with degree from any accredited college also accepted.
7. Students with two years of college admitted to emergency course only.

SCHOOLS FOR CLINICAL LABORATORY TECHNICIANS

The original survey of 196 schools for clinical laboratory technicians was published in *THE JOURNAL*, Aug. 29, 1936 together with the first list of 96 approved schools. Essentials had been formulated by the Council on Medical Education and Hospitals of the American Medical Association with the cooperation of the American Society of Clinical Pathologists and ratified by the House of Delegates of the American Medical Association in May 1936.

The Council approves 243 schools for clinical laboratory technicians in forty states and the District of Columbia. Last year 18 schools were added to the Council's list. All of the approved schools provide adequate hospital experience under satisfactory supervision of qualified instructors. The scope of teaching material and the rotation of assignments has in each instance been determined sufficient to give students a broad training and experience. Average enrolment in these schools is small and thus individual instruction is encouraged.

Many factors influence the maximum number of students admitted to these schools. This year the total maximum capacity amounts to 1,783 students, or an average of $7\frac{1}{3}$ per school. The theoretical maximum capacity, if determined by the number of instructors, would total about twice this number.

A total of 1,034 students were graduated from all the approved schools during 1943, or an average of $4\frac{1}{4}$ graduates per school. This is the second year in succession that the average number of graduates per school has declined, although there has been a net increase in the number of approved schools each year. More effort must be devoted to increasing the number of graduates from approved schools. Otherwise hospitals, clinics and physicians will be forced to rely on individuals whose background of training and experience is definitely inferior to the standards that have been set for qualified technicians. The seriousness of this problem is emphasized by the fact that last year hospitals reported an increased employment of 2,383 full time and 238 part time clinical laboratory technicians, while only approximately 1,000 were graduated. Last year the Council on

Medical Education and Hospitals urged that every justifiable effort should be made to increase the number of students. Now, with the employment of large numbers of "technicians," many of whom undoubtedly have not had sufficient preparation, and with the apparent demand for more technicians this year, the problem of adequately training sufficient numbers of technicians is more acute.

Last year 64 per cent of the schools admitted students with the minimum prerequisites. This year 68 per cent require two years of college credit, while 18 per cent select applicants who have had three years and 14 per cent demand a college degree. This tendency to accept students with the minimum entrance requirements seems to be more common in the new schools.

Approximately 82 per cent of the schools offer twelve months of training, while only 11 per cent present eighteen months of organized instruction and experience to their students. These data represent a slight increase in the minimum of twelve months of training. No tuition fee is reported by 132 schools, or 54 per cent of those approved. Average tuition for all schools, except the 29 which require university fees, amounts to \$41. This is a sizable decrease in the average tuition. Only 16 per cent of the schools charge more than \$150. The highest tuition, excluding university fees, is \$300.

Affiliations exist between the approved schools and accredited colleges in 126 instances, or 51 per cent of all schools. Most of these affiliations result in a complete year of college credit for time devoted to the hospital training. Such an arrangement permits the student to obtain a degree from the college if three years or more of acceptable credits have been earned prior to the hospital training.

Correspondence regarding schools for the training of clinical laboratory technicians should be addressed to the office of the Council on Medical Education and Hospitals. Graduates of approved schools desiring registration should communicate with the Board of Registry of Medical Technologists, Ball Memorial Hospital, Muncie, Ind.

APPROVED SCHOOLS FOR CLINICAL LABORATORY TECHNICIANS

Council on Medical Education and Hospitals of the American Medical Association

NOTE: Under "Tuition" the letter B indicates that a breakage fee is charged; the letter U indicates university fees. Degrees mentioned in last column are granted by affiliated colleges and universities. Students lacking the scholastic requirements should contact the registrar of the college or university and not the hospital. Those who wish to enroll in a course given by the college or university or who desire to transfer their credits should correspond with the registrar and not the hospital.

- a. Male students are admitted.
b. Only students from affiliated college admitted.
1. Students in eighteen-month course leading to M.S. degree allowed thirty-six quarter hours; entrance requirements—B.S. degree; tuition, \$100.
2. Students enrolling in four-year degree course are allowed twenty-

- five semester hours for final year spent in hospital; these students pay regular university fees.
3. Additional affiliations include: Western Mich. Coll. of Education (30 sem. hrs.) and Central Mich. College of Education (32 sem. hrs.).
4. Students with degree admitted to twelve-month course.

SATURDAY, MARCH 25, 1944

HOSPITAL SERVICE IN THE UNITED STATES

In war as in peace the hospitals of the United States continue to render faithful and efficient service to the sick and injured of the nation. The tremendous task they assume under wartime conditions is illustrated in the annual hospital report of the Council on Medical Education and Hospitals published in this issue of THE JOURNAL. The number of patients admitted in 1943 reached the unprecedented total of 15,374,698, as compared with 12,545,610 in 1942. In addition there were 1,924,591 hospital births, an increase of 253,992 over the previous year. Similarly the daily patient load or average census increased by 131,096, not counting newborn infants. Equally impressive is the expansion of hospital beds from 1,383,827 in 1942 to 1,649,254 in 1943. This increase of 265,427 beds is the equivalent of a new 727 bed hospital for each day of the year. When this recent growth is compared with the average annual increase of 25,000 to 30,000 beds in the twenty year period that preceded the war, the extent to which hospital facilities have been developed in relation to wartime needs may be better appreciated.

The greatest gain has naturally occurred in the federal group, whose admissions increased by 2,356,885 in the last year. Significantly the state, county and municipal hospitals showed a decrease of 103,733, while the non-governmental group comprising the church related institutions, other nonprofit associations and the proprietary hospitals had a substantial increase of 575,936. Although several factors may be involved, the influence of improved economic conditions is clearly evident in the changes that have occurred in the nonfederal hospital groups. The general hospitals constitute the largest division in the classification of hospitals according to type of service. They have 51 per cent of the bed capacity but received 94 per cent of all patients admitted in 1943. Their participation in the recent expansion of hospital service can be measured by an increase of 2,820,350 admissions during the year.

The average length of stay in the general hospitals was identical with that reported in 1942 except in the federal, state and city-county groups, which showed reductions of one to two days. The average in the governmental hospitals, however, remained at nineteen days as in the previous year because of the large increase of patients in the federal group, in which the longest stay occurred. In the nongovernmental general hospitals the patients had an average stay of ten days. There was a decrease in the percentage of bed occupancy in the federal and general hospitals. This reduction in the face of a greatly increased admission rate is primarily the result of a rapid expansion of federal hospital facilities in anticipation of future needs. The occupancy rate in these institutions therefore has not kept pace with the number of beds available for hospital care.

A special feature this year is a study of hospital facilities available for the segregation and care of contagious diseases throughout the country. This includes not only the isolation hospitals but also the units maintained by other institutions for regular isolation service or temporary hospitalization of patients awaiting transfer to other contagious disease departments. Reports are also included regarding schools of nursing education and administrative, nursing and technical personnel in all hospitals. While these show the number of individuals employed in each classification, they do not indicate the turnover of personnel or the difficulty that many hospitals experience in obtaining the required number of trained workers to maintain essential hospital functions.

Attention is called to the extraordinary completeness of the present report in relation both to civilian and to military hospitals. Information as required for tabulation purposes and the hospital list was received from nearly 99 per cent of the 6,655 hospitals now registered by the American Medical Association. For reasons of military security many of the newly established hospitals in the federal group are not listed in the Register; they are, however, included in the tabular and statistical data published by the Council. Grateful acknowledgment and appreciation are extended to all who cooperated in making this report possible. The hospitals which supplied information to the Council have also been of service to the country at large, for the annual hospital reports of the American Medical Association have become increasingly valuable in relation to wartime needs and are widely utilized by federal agencies, civilian groups and individuals concerned with hospital activities and allied services.

Many of the hospitals have rendered increased service while operating with reduced staffs of physicians, house officers, nurses, technicians and general and special service personnel. Their accomplishment in the face of these difficulties reflects not only a high degree of

standardization but also the initiative, pride of occupation, loyal cooperation and devotion of those who serve the sick. By careful administrative management, coordination of services and skillful utilization of available facilities and personnel the increased demands of the wartime period have been met.

SECRETION OF A GLUCOSE OXIDIZING ENZYME WITH BACTERIOSTATIC PROPERTY BY *PENICILLIUM NOTATUM*

In 1936 Hirsch described a method of measuring the respiration of bacterial aerobic cultures; this enabled him to follow the course of the bacterial growth and also to gage bacteriostatic and bactericidal actions without resorting to subculturing. He and his collaborators, working in the Institute of Hygiene of the University of Istanbul, were able in 1942 to throw some light, by the use of this method, on the antibacterial action of the sulfonamides. Applying a similar method to a study of the bacteriostatic effect of penicillin, they demonstrated¹ that the penicillin secreting strain of *Penicillium notatum* (Fleming) spontaneously produces a glucose oxidizing enzyme with antibacterial properties. This enzyme is promptly inactivated at 100 C.

The enzyme can be extracted from the culture filtrate with benzoic acid. It acts on dextrose only and not on any other carbohydrate or carbon compound. One-half mol of oxygen is consumed in oxidation of 1 molecule of glucose. Oxidation of glucose takes place without splitting off carbon dioxide, the final product of oxidation being gluconic acid. By the action of a dialyzed culture filtrate, 22 Gm. of calcium gluconate is obtained from 20 Gm. of glucose (92 per cent of the theoretical amount). The optimal hydrogen ion concentration of the enzymatic activity is shifted with progressive transformation from a p_H of 5.5 to a p_H of 6.5. The enzyme is still active at 25 C. The optimal temperature for its activity has not thus far been determined. The activity of the enzyme is increased by alpha amino acids, in particular by diamino acids, by peptones and proteins and also by gelatin, insulin and bacterial proteins.

The enzyme seems to be identical with the widely distributed fungus enzyme (glucose oxydase) which Miller obtained under high pressure from *Penicillium glaucum* and *Aspergillus niger*. The spontaneous secretion of the enzyme has so far been observed only in *Penicillium notatum*. The secretion of the enzyme is accelerated with increasing concentration of a phosphate buffer in the nutrient medium of the fungus. Considerable enzyme secretion begins in the presence of one-

tenth molar phosphate buffer (p_H 6.4) on about the fifth day and reaches its peak on the eighth or ninth day. The myceliums of *Penicillium notatum* of Westling and of *Penicillium glaucum* do not produce an enzyme under the same conditions.

The antibacterial action of the enzyme discovered by Hirsch depends on the presence of glucose and oxygen; in other words, the action depends not on the substance of the enzyme but on the enzymatic reaction of the glucose oxidation. The active enzyme is effective against *Staphylococcus aureus* but not against *Escherichia coli*. The respiration of "resting" staphylococci is not reduced by the enzyme, and a bactericidal effect cannot be demonstrated. However, the enzyme manifests a pronounced bacteriostatic effect. With moderate enzymatic activity the rate of the increase in the numbers of staphylococci is affected.

INTERNSHIPS IN WARTIME

Under the 9-9-9 program of the Procurement and Assignment Service to meet military needs, the hospital internship has been reduced to nine months. Although changes in organization of training programs have naturally occurred, the internship continues to provide basic preparation for general practice, specialization, military medicine or other medical activities.

Every effort is being made to maintain a high level of educational performance. The reduction in length of internship, therefore, imposes a greater responsibility on hospitals to insure that the limited period of training will be productive of maximum educational value. First, the internship must continue to be viewed primarily as an educational function and not mainly as a personnel problem in relation to institutional service. With the present shortage of personnel of all kinds, hospitals and medical staffs must guard carefully against any tendency to exploit interns in noneducational duties. Economy in the use of house officers is of the utmost importance. Any assignment, therefore, which does not contribute materially to the training program should be eliminated, so that the intern's time may be devoted to essential hospital and educational needs.

The internship is fundamentally an educational service. In this service theoretical knowledge is translated into practical experience under the guidance of a competent hospital staff. Successful organization requires careful administrative planning, thorough analysis of individual assignments, readjustments of schedules and case loads as necessary, and effective bedside teaching. When a hospital is functioning with a shortage of house officers, clinical assignments need to be kept within such limits as will insure efficient medical care, sound educational service and adequate protection of the intern's health. Excessive case loads in which interns

1. Hirsch, Julius: Die Sekretion eines Glukose-oxydierenden Enzyms mit bakteriostatischer Wirkung durch *Penicillium notatum* Fleming, Istanbul Seririyati 25, No. 8, 1943.

are submerged in a multiplicity of routine procedures will seriously impair the quality of instruction.

From recent reports it is apparent that the loss of medical personnel and the reduction in house staffs have affected the ability of some hospitals to maintain a satisfactory program for necropsies. In view of the importance of pathologic studies in relation to intern education it is strongly urged that hospitals with low necropsy rates immediately exert every effort to obtain sufficient material for instruction. The ratio of necropsies, it should be noted, has long been considered a reliable index of the quality of educational service in hospitals.

In the final analysis the success of an intern training program depends on the cooperation of the medical staff and the willingness and ability of individual physicians to carry the added burden of teaching as their contribution to medical education and the future of American medicine.

Current Comment

TECHNICAL PERSONNEL IN MEDICAL SERVICE

Attention has been focused on the need for technical personnel in hospitals, clinics and physicians' offices. To conserve the time of physicians who remain in practice, hospitals and clinics are attempting to acquire an increased number of skilled assistants. The situation is complicated by the need of the armed forces for many of these workers. The present requirements of the armed forces for additional technical personnel include 20 per cent of the qualified dietitians, 60 per cent of the qualified physical therapists and over 60 per cent of the qualified occupational therapists. Several hospitals report that they do not have their normal quota of experienced technicians and are forced to limit the work of their departments. The number of unfilled positions in civilian hospitals that require qualified technical personnel approximates one twelfth the number of dietitians, one fifth of the occupational therapists and perhaps a similar proportion of physical therapists and medical record librarians. To meet these requirements it is apparently necessary to train enough technicians to equal large percentages of present qualified personnel. The requirements amount to over 80 per cent of present occupational therapists, 80 per cent of present physical therapists, 28 per cent of present dietitians and over 20 per cent of present medical record librarians. Data on the technical personnel in hospitals can be found on pages 849 and 916 to 922 of this issue of *THE JOURNAL*. Here it may be noted that 50,326 specially trained personnel were engaged in 1941, 61,181 in 1942 and 73,174 in 1943. Many of these, it is recognized, have not received a complete course of training and must necessarily work under the supervision of others who are fully qualified in these fields. Further

efforts are necessary to increase the supply of technical workers for civilian and military hospitals. Rehabilitation will create additional demands. When the war is won and physicians return to resume their places on the staffs of civilian hospitals there will be requests to enlarge or create new departments of physical therapy, occupational therapy and so on because of the importance of these forms of treatment, especially in army hospitals. Hospitals that can function as training centers for technical personnel are urged to do so. The Council on Medical Education and Hospitals of the American Medical Association has outlined minimum essentials for the approval of schools for clinical laboratory technicians, physical therapists, occupational therapists and medical record librarians. The essentials for x-ray technician schools are being prepared.

SUCCESSFUL TREATMENT OF CARBON TETRACHLORIDE POISONING

Millions of pounds of carbon tetrachloride are used annually in this country, and cases of poisoning are not rare. Therapy has not been notably successful. A promising new treatment now comes from the combined efforts of physicians at a United States Military Hospital, E. T. O., and the Bernhard Baron Research Laboratories, Royal College of Surgeons of England.¹ The report is based on a single case of absorbing interest which concerned an army air force pilot who accidentally ingested a large quantity of carbon tetrachloride. The report notes that the maximum therapeutic dose is 4 cc. but that fatalities have been reported with doses as low as 1.4 cc. In the case reported the amount swallowed was 30 to 40 cc. and the indication was that the drug was completely absorbed, the immediate onset of symptoms indicating a rapid entry into the circulation. Vomiting in this case was not induced until forty-five minutes after ingestion. Enlargement of the liver with the edge palpable 2 inches below the costal margin in the right anterior axillary line was demonstrable some nineteen hours after the carbon tetrachloride had been swallowed. About twenty hours after the ingestion the patient was given 2 Gm. of *D,L*-methionine by mouth. This was retained, and three hours later 1 cc. of a casein-digest-methionine solution was injected slowly into an antecubital vein. Since this was not followed by any immediate reaction, 5 cc. more was injected, also without reaction. Continuous infusion of the solution by a drip apparatus was then begun, the rate of infusion being about 2 cc. per minute. By the end of the next three hours, when 436 cc. of the solution had been infused, the patient complained of chilliness, intense headache and backache, and some aching of the limb muscles. The infusion was then stopped. The liver at this time was still tender and had enlarged considerably; the edge, which was rounded, had reached the umbilicus at the midline. The next

U. S. ARMY TRANSPORT ERNEST HINDS DESIGNATED AS ARMY HOSPITAL SHIP

The United States Army transport *Ernest Hinds* was designated as a United States Army hospital ship January 3, in accordance with international practice, as set forth in the provisions of the Hague Convention X of 1907. In the future the United States Army hospital ship *Ernest Hinds* will be operated in accordance with the provisions of applicable treaties. Notification of this designation was delivered through channels to the Hungarian and Rumanian governments on January 17, to the German, Japanese and Thai governments on January 18 and to the Bulgarian government on February 4.

SUPER RED CROSS MARKER FOR STATION AND GENERAL HOSPITALS

The Army Medical Department has developed a new super red cross canvas marker measuring 100 feet by 100 feet for use by station and general hospitals in combat zones, the War Department announced recently. The huge marker is plainly recognizable from a height of 25,000 feet. It is made of heavy canvas and will withstand all types of weather. Special attachments provide for anchoring it firmly to the ground. It is being manufactured by the Quartermaster Corps at Jeffersonville, Ind., depot and was developed at the direction of Major Gen. Norman T. Kirk, Surgeon General, U. S. Army.

The Army Medical Department now uses a canvas removable type red cross marker to designate hospital tents in combat

areas. The marker measures 21 feet 6 inches by 9 feet 6 inches and has two crosses, each 8 feet square, so that when it is thrown across the sloping tops of hospital tents the large red cross marking can be seen from any angle to designate the tent as a hospital tent. It attaches easily to the tent ropes and can be put in place or removed quickly. This marker will continue to be used to designate the smaller hospital tents, while the large 100 foot red cross is to be used for station and general hospitals only.

ARMY PERSONALS

The post commander at Fort Knox, Kentucky, recently announced the promotion of Leonard Long, formerly of Bluffton, Ind., from captain to major in the Medical Corps of the Army of the United States. Dr. Long is the chief of x-ray service at the station hospital at Fort Knox. He graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1932 and entered the service July 13, 1941.

Dr. Thomas M. Fullenlove, formerly of San Francisco, flight surgeon attending the Mustang pilots who initiated the new long range fighter in combat over Europe, was recently promoted from captain to major, according to an announcement by the Mustang headquarters in England. Dr. Fullenlove graduated from the University of Louisville School of Medicine (Ky.) in 1934. After entering the service in June 1942 he attended the School of Aviation Medicine at Randolph Field, Texas. He accompanied the Mustang group overseas and has been flight surgeon on combat status since the group went into action Dec. 1, 1943.

MISCELLANEOUS

EMERGENCY MATERNITY AND INFANT CARE

A Message from the Surgeons General of the Army and Navy to the Physicians of the United States

On March 18, 1944 the Emergency Maternity and Infant Care program for the wives and infants of enlisted men in the four lowest pay grades of the armed forces of the United States will have completed its first year. Approximately a quarter of a million wives and infants will have been given care under the program. More than 90 per cent of this number are wives of enlisted men; nearly 10 per cent are their newborn infants. Medical, nursing and hospital care is being made available in army and navy installations where it does not interfere with the care of the soldier and where it can be given without increasing existing facilities. Whatever other care is available in the place where the wife and infant are living is being given through the civilian authorities.

Physicians the country over are contributing their medical skill to this wartime program generously and in return for moderate recompense. Hospitals the country over have opened their doors to these wives and their infants making available accommodations where their medical needs can be met adequately, though without luxury care. Nurses the country over are helping in the city and the rural homes and in the hospitals.

All this is being carried out voluntarily by those who are participating in the program. All this is being done in spite of the great shortage of physicians and nurses serving the civilian population—a shortage caused by the entry into the armed forces of thousands of our physicians and nurses.

This program of maternity and infant care for wives and infants of enlisted men is made possible by grants from the federal government through the Children's Bureau of the Department of Labor and the state health agencies for the purpose of relieving anxiety among the enlisted men as to how the costs of maternity care for their wives, or the costs of medical care for their infants, will be met in their absence from home while in the armed forces—when, for a great majority, their family income has been lowered materially. The program carried out by the state health agencies brings assurance to the enlisted men that their national and state governments are doing whatever is in their power to make care available to

their wives and infants, that physicians throughout the country are helping.

The morale in the armed forces is being raised and our fighting men go overseas with greater confidence in the security of their families because of this wartime program.

We who are responsible for the health and medical care of the men in the armed forces are grateful to you—physicians, nurses and hospitals—who are participating in this program of care of the wives and infants of these men. You are sharing with us our normal peacetime responsibility of caring for the families of our men and so are making it possible for us to give our best efforts to the men themselves.

Your contribution is an invaluable aid to us in the prosecution of the war, and we count on your carrying this program forward in the year to come with the same generous spirit you have shown in the past year.

ROSS T. McINTIRE,

NORMAN T. KIRK,

Vice Admiral, M. C., U. S. N., Major General, U. S. Army,
The Surgeon General of the Navy. The Surgeon General.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, March 18, p. 783)

ILLINOIS

Ravenswood Hospital, Chicago. Capacity, 163; admissions, 5,812.
George Swanson, Superintendent (interns—October 1).

IOWA

Mercy Hospital, Cedar Rapids. Capacity, 147; admissions, 3,862.
Sister Mary Mercy, R.N., Superintendent (2 residents, 1 intern).

OHIO

Aultman Hospital, Canton. Capacity, 150; admissions, 6,332. James W. Stephan, Director (interns).

TEXAS

Methodist Hospital of Dallas, Dallas. Capacity, 176; admissions, 7,387;
Cicero B. Fielder, Administrator (1 resident—August 15).

**REPORT MADE BY SPECIAL FIVE MAN
MEDICAL COMMISSION**

The commission of five physicians (THE JOURNAL, January 15, p. 166) appointed by the President Dec. 30, 1943 to study the requirements of personnel for admission to the armed services presented its report recently. It obtained factual data, comments and opinions regarding numbers of men potentially available for induction, the numerical needs of the armed services for manpower, the rates and causes for rejection under the present requirements for admission, the type of duty for which men are needed by the armed services and the possible effect of the current requirements for admission on claims for postservice benefits from approximate civilian and military agencies of the government and examined the requirements for admission to the Army, Navy and Marine Corps in the light of this information, reaching the following conclusions:

1. The physical requirements for admission to the armed services cannot be reduced below those contained in appendix III without impairing the efficiency of these services.

2. The services have reached saturation for newly inducted men for limited service, since the need for men in this category will be fully met by men already in service who as a result of incidents of the service are no longer fit for general service.

3. It is evident that the urgent and increasing need of the services today is for men for general service and that this need will progressively increase until the war is successfully concluded.

Distribution of Registrants Ages 18-37 as of Dec. 1, 1943

Total living registrants.....	22,138,000
In the armed forces (inducted).....	6,540,000
In the armed forces (enlisted).....	2,430,000
Disqualified after physical examination.....	3,357,000
* In process of classification, examination or induction	1,090,000
Deferred, occupational reasons.....	3,834,000
Deferred, dependency reasons.....	4,645,000
Deferred, other reasons.....	152,000
Unclassified and unknown.....	90,000

* This group includes 43,000 men who have been found qualified for induction for limited service under present requirements but whose services have not been required by the armed forces in this status.

4. It is apparent that these needs cannot be met by lowering the physical requirements for admission to the armed forces or by increasing the induction of men for limited service.

5. In view of the needs of the armed services for men qualified for general service, which needs cannot be fully met from the pool of men now on hand in class 1-A plus the annual increment of men coming of military age, it is apparent that the manpower required for the prosecution of the war cannot be obtained except by induction of men living with their families and recourse to all other available sources.

The director of the Selective Service System presented the rates and causes for rejection under the current requirements for admission to the armed services as shown in the table.

WARTIME GRADUATE MEDICAL MEETINGS

Additional subjects and speakers for Wartime Graduate Medical Meetings have just been announced for March 29, 30 and 31 at Bruns General Hospital, Santa Fe, N. M. They include the following speakers and subjects:

Discussion of Shoulder Disabilities, Dr. Atha Thomas.

Certain Phases of the Problem of Bowel Obstruction, Dr. Owen H. Wangenstein.

Symposium on Peripheral and Disseminated Vascular Disease, Drs. N. W. Barker, Alton Ochsner and Paul Klemperer.

Tropical Medicine, Dr. E. R. Murgage.

Psychosomatic Medicine, Dr. Karl Menninger.

Neurologic Conditions, Dr. Rudolph Jaeger and Dr. Atha Thomas.

Problems in Rheumatic Fever, Dr. A. W. Harris and Col. J. E. Benjamin.

Renal Disease, Dr. Thomas Addis and Dr. H. T. Low.

Others on the program are Major F. J. Fischer, Lieut. Col. J. D. Koucky, Lieut. Col. G. J. Kastlin, Lieut. Col. C. W.

Irish, Major H. E. Schmidt, Capt. F. J. Putney, Capt. E. P. Hausner, Major F. L. Larkin and Major S. I. Kooperstein. Brig. Gen. Larry B. McAfee, commanding general of the hospital, will give the address of welcome.

**AMERICAN RED CROSS TO SEND
AID TO LITHUANIA**

Medical and hospital relief supplies valued at \$10,000 are being prepared by the American Red Cross for shipment to Lithuania, it was announced recently by Norman H. Davis, chairman. This shipment, in response to needs verified by neutral observers, will go forward to the Baltic country as soon as the American Red Cross can procure the necessary cargo space. It will be followed later by another consignment of medical supplies to be paid for by a special donation of \$3,000 made to the Red Cross by the Lithuanian minister to the United States, Mr. Povilas Zadeikis. The first shipment will consist of simple drugs and disinfectants such as boric acid, ether, iodine, mercurochrome, phenol, castor oil and viosterol. Included also are hypodermic needles and syringes, as well as one thousand thermometers.

**AMERICAN BUREAU FOR MEDICAL
AID TO CHINA, INC.**

The American Bureau for Medical Aid to China, Inc., with headquarters at 1790 Broadway, New York 19, is an organization whose primary purpose is to cooperate with China in strengthening the Chinese health system. The organization was founded in 1937 by a small group of Chinese doctors and merchants in this country who banded together to send China urgently needed medical supplies. The directors of the bureau are doctors, scientists and businessmen, both Chinese and American. ABMAC works through agencies of the Chinese government and the National Red Cross Society of China. In 1941 ABMAC became one of the agencies participating in United China Relief and turned all fund raising activities over to that organization. Although it no longer makes any direct appeals for support, ABMAC welcomes contributions sent to its headquarters. Such donations are counted as part of the total funds raised by United China Relief.

SAFEGUARDING MILITARY INFORMATION

The Civilian Defense Volunteer Office of Greater New York in cooperation with the Army, Navy and Federal Bureau of Investigation is sponsoring "Safeguarding Military Information," a campaign to put every man, woman and child on the constant alert against enemy sabotage. The enemy, with agents in all sorts of unexpected places, has his ears constantly open for even seemingly innocent bits of information about the fighting forces, and piecing little bits together is a precision art with him. To be on the safe side . . . to safeguard all military information . . . think first before you spread the word that may mean death to our men and destruction to our plans. No one can be hurt by things left unsaid.

**DR. HENRY LADD STICKNEY APPOINTED
PORT MEDICAL SUPERVISOR**

Dr. Henry Ladd Stickney, Rockport, Mass., has been appointed by the War Shipping Administration as post medical supervisor of the port of Boston, which includes all of the Northeast, except Connecticut. His chief duties are to board incoming ships, meet trains and planes and examine wounded and ill merchant marine seamen and see that they are properly hospitalized. Headquarters are at Hotel Bostonian, 1138 Boylston Street, Boston.

**BAUER AND BLACK ADDS SECOND
WHITE STAR TO E PENNANT**

Bauer and Black, Chicago Division of the Kendall Company, and first surgical dressings house to win the E award, has now been awarded the second white star—for continued excellence in production—to add to its pennant.

APPEAL TO HOSPITALS AND PHYSICIANS IN WASTE PAPER DRIVE

The War Production Board regional offices throughout the country are asking for the cooperation of every hospital, every doctor, every medical and dental unit in the scrap paper program. They are asked to dispose of books, magazines, newspapers, records, wrappings, cartons, advertising literature and bulletins and to ferret out every last scrap or shred of paper to go into the salvage paper drive. Unless adequate supplies of waste paper can be moved to the mills, the curtailed paper and paperboard production will seriously retard the war program and will have even more serious effects on civilian uses of paper. Hospitals, doctors' offices and other medical and dental centers that depend on packaging to safeguard supplies have a direct stake in salvaging raw materials for continued production of paperboard. They have an even greater obligation to see that military and naval hospitals are given full supplies of paper through assistance in the waste paper salvage program.

Reprinted from the Chicago Daily News, Jan. 6, 1944.

Hospitals can be especially helpful in the waste paper drive by publicizing the campaign to all doctors whose offices are fruitful and profitable sources of old magazines, newspapers, bulletins and records. It has been suggested that hospitals urge doctors to send or bring their waste paper to the particular hospital which they serve as one means of aiding them to dispose of it with a minimum of effort. Desks, both in doctors' offices and in hospitals, are generally good sources of scrap and should not be overlooked. One Chicago hospital, for example, is supervising the huge task of micro filming all the hospital's records for the last forty years and contributing the original records to the scrap heap. Micro films will form more permanent and safer records, and at the same time sufficient floor space is being conserved to provide additional bed space. Several other hospitals are preparing to have their records micro filmed also. Since micro film machines cannot be purchased at present, they can be rented from local sources, the names of which will be furnished by the local War Production Board office. However, micro filming of old records is only one step that can be taken to swell the nation's paper scrap piles. Each hospital or physician is asked to check the following sources of waste paper: old files, ledgers, correspondence, receipts, canceled checks, time cards, invoices, pamphlets, calenders, bulletins,

obsolete catalogues, books and periodicals, containers, flower boxes and waste baskets.

Unused paperboard containers are particularly in demand, and the large number that come into hospitals regularly should be carefully conserved and turned back for reuse. Corrugated and solid fiber containers and setup paper boxes should be carefully collapsed, tied into bundles and turned over to a scrap or container dealer. More than a billion containers will be required in 1944 for the armed forces and lend-lease. While the armed forces in this country return containers for reuse, those overseas cannot. But every hospital can put its used containers back into circulation. In this lies the solution to the critical shortage of home front containers, the only way to keep medical and hospital supplies moving, a way every hospital can help the war effort and itself.

Hospitals handle paper and other salvage in one of two methods: (1) contract with a salvage dealer to collect, handle and dispose of all the hospital's salvage at regular intervals or (2) the hospital itself collects the salvage, bales, bundles or shreds it and disposes of it direct to a dealer or mill. Both paper balers and shredders can be obtained today, and hospitals seeking to purchase them should consult the local War Production Board officials.

The War Production Board estimates that more than 1,250,000 tons of salvageable paper is available every month, and a half of this will keep the mills running at peak production. Shipments of waste paper to the mills must be increased at least 167,000 tons (33.5 per cent) a month. No part of the war effort is more essential than the waste paper drive, and the hospitals of America are asked to shoulder their share of this job today.

PRODUCTION OF PENICILLIN BEING INCREASED

The Office of War Information reported recently that penicillin is being manufactured by thirteen American and two Canadian firms in continually increasing amounts and that by July 1944 the Chemical Bureau of WPB anticipates that twenty-one United States firms will be producing penicillin at full capacity. However, in spite of greatly increased production the U. S. armed forces do not have as much penicillin as they need and for some time the Army and Navy will have first call on supplies of this drug. In order to stretch supplies as far as possible, Army and Navy hospitals are restricting the use of penicillin to men whose wounds or diseases do not respond to treatment with the sulfonamides. The amount of penicillin available for civilian use at present is sufficient only to supply hospitals studying the effects of the drug. Distribution of penicillin for clinical research among civilians has been assigned by the Office of Scientific Research and Development to a committee of five physicians headed by Dr. Chester S. Keefer, Evans Memorial Hospital, Boston. Civilian requests for penicillin must be made of Dr. Keefer by patients' doctors. As a result of increased production resulting from intensive research carried out in laboratories of the U. S. Department of Agriculture and in industry, the price of penicillin has decreased from \$20 per hundred thousand units when it was first commercially manufactured in 1943 to \$4.75 per hundred thousand units, and further price reductions are anticipated.

The Chemical Bureau of WPB states that the principal reason for the scarcity of penicillin is the difficulty of production. Manufacture requires critical equipment such as refrigeration machinery, centrifuges, vacuum pumps, tanks and special packaging devices. The fermentation cycle is unusually long, and exacting conditions of sterility, temperature and atmosphere control are required to obtain any yield whatever. More than 20 quarts of culture fluid is required to yield 1 Gm. of the dry powder. Work is still being done to determine the most productive strains of mold and to improve culture mediums, methods of extraction, purification, standardization and packaging. Chemical research studies are being carried on for determining the structure of penicillin. Authorities agree that preparation of penicillin synthetically would greatly speed up production.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Fortieth Annual Meeting, Held in Chicago, Feb. 14 and 15, 1944

DR. RAY LYMAN WILBUR, Stanford University,
Calif., Presiding

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

FEBRUARY 14—MORNING

DR. RAY LYMAN WILBUR, Stanford University, Calif.: This address appears in full in this issue, page 815.

PROBLEMS OF POSTWAR MEDICAL EDUCATION

The Medical School Program

DR. HAROLD S. DIEHL, Minneapolis: This paper appears in full in this issue, page 819.

Hospital Training of Medical Graduates

DR. SAMUEL SOSKIN, Chicago: The Michael Reese Hospital is in the process of reorganizing its clinical services. We are preparing to help meet the postwar demand for hospital training and for refresher courses. We expect to accept a larger number of residents and assistant residents than we did before the war. We also expect to offer refresher courses for visiting physicians. We believe that the greater proportion of resident staff to available clinical material will necessitate the more intensive use of the latter for teaching purposes. We are therefore systematizing our routine so as to leave more time for demonstration periods and for didactic classes. With regard to the refresher courses for visiting physicians, we are fortunate in having at our institution a number of full time men working in the basic medical sciences, so that this portion of our postgraduate training program will offer no great difficulties. However, as at most hospitals, most of our clinical men are in the private practice of medicine. It is therefore necessary to arrange our program so that these men can undertake heavier teaching schedules while at the same time they continue to take care of their practices and make their living.

There are two factors whose influence on the picture as a whole it is very difficult to assess at the present time. These are, first, the rate of demobilization of physicians from the armed services and, second, the economic status and drives of those physicians at the time. The quantitative aspects of training facilities could be quite different, depending on whether the demobilization occurs over a period of one year or of five years. The qualitative aspects will depend to some extent on whether or not it will be possible to arrange for the early demobilization of teachers. The economic status will certainly have to be considered in determining how long and how intensive postgraduate courses should be. For those physicians who wish to resume their practices in or near a medical center, postgraduate courses confined to half-days might be most suitable. It would enable the trainee to devote the other half-days to building up his practice. But this arrangement would of course increase the time which the out of towners would have to spend away from his community. Probably both the full-day and the half-day type of program should be available at different institutions in each medical center. The necessary estimates of future conditions and needs, and the appropriate arrangements to meet those conditions and needs, can be made only by a joint committee including representatives of the hospitals, medical schools, the American Medical Association, the specialty boards, the armed forces and the government. After its planning was done, this

committee could continue to function as a central information and distribution agency.

The prewar specialist who has served in the armed forces as a specialist would seem to present no training problem. On the contrary, the wealth of experience gained under war conditions should enhance his value as a teacher. He may or may not desire a temporary association with a diplomate of his specialty board for purposes of reorientation in peacetime work. But, in any case, advantage should be taken of his special experience in amplifying the postgraduate courses, not only for the benefit of physicians returning from the armed forces, but also for those whose lot it was to remain behind and look after the civilian population.

Readjustments of Returning Medical Officers

DR. WILBURT C. DAVISON, Durham, N. C.: This paper appears in full in this issue, page 816.

Postwar Financing of Higher Education

FRED J. KELLY, PH.D., Washington, D. C.: I agree with the Armed Forces Committee on Postwar Educational Opportunities for Service Personnel, which said in its report to the President last July "the primary purpose of any educational arrangements which we may recommend should be to meet a national need growing out of the aggregate educational shortages which are being created by the war." There is no reason to minimize technological and medical education in the postwar period merely because it is imperative to emphasize liberal education. Liberal education should be used to leaven other education somewhat more than has been true in the past and thus in a greater measure fuse liberal and professional education. At any rate there must be no competition between liberal and professional education in the postwar swing of the pendulum. The sooner educational statesmen go to work to develop some ideas along the line of economy, the more surely we shall avoid some enforced economies which may not so well protect the quality of higher education.

There seems little doubt that the Congress will pass some form of bill for the education of veterans of World War II. Practically all the pending bills agree on two points: (a) Living expenses will be provided to all ex-service men and women who pursue satisfactorily a course in an approved educational institution and (b) educational institutions which provide the instruction will be paid for their services. Considerable variation exists among the several bills with respect to methods of carrying out these two purposes, but probably the Barden bill offers the most widely accepted plan. If it passes and the process of general demobilization starts by the middle of 1945, it will provide at least a short period of education for an estimated 1,000,000 men and women and an additional one, two or three years for possibly 200,000. What this will mean financially to the institutions is not clear in all respects.

The prospect for gifts appears brighter to me than to many with whom I talk. Persons and corporations whose income is rather large are coming to see that a gift to an educational institution costs them much less than the face value of the gift. If the national income can be kept at a high figure, the fact that it is distributed among a larger number of persons than formerly may be an advantage to the recipients of gifts. It will make it necessary, however, for the colleges to sell the idea of their worth to a larger circle of friends, and probably more critical ones.

The states have accumulated considerable reserves during the war because they have not reduced their levies as the tax bases—property and income—have increased. Hence it might appear that they could increase appropriations. But as federal taxes now increase there is likely to be a reaction against maintaining the present state tax levies. This reaction may come at

about the same time as inflationary influences are stemmed and property values and incomes decline. As a result of all the confusing and conflicting factors affecting appropriations to be made by state legislatures there is likely to be wide differences in the reactions in various states. Some states may treat higher education generously; others conservatively if not parsimoniously.

Summarizing, postwar financing of higher education faces five problems:

1. It must avoid the danger of imbalance among the several curriculums as the pendulum swings away from technological training.

2. Higher education must be prepared for a more critical attitude during deflation and put its own house in order by squeezing out most of the water in its administrative and teaching procedures.

3. The program for returned soldiers will provide a period of easy financing for the colleges but will tend to encourage cheaper education and jeopardize somewhat the traditional assumption that the cost of higher education should be borne by the state rather than by the student.

4. Income from gifts will be on a broader base of givers, but high income taxes may encourage giving.

5. To be on the safe side in the matter of state appropriations, institutions should take unusual steps to assume the appreciation of their services by an increasing proportion of people.

Distribution of Medical Care

DR. SAMUEL PROGER, Boston: This paper appears in full in this issue, page 823.

FEBRUARY 14—AFTERNOON

WARTIME PROBLEMS IN MEDICINE AND MEDICAL EDUCATION

The Army Medical Officer in Action

MAJOR GEN. GEORGE F. LULL: Two of the important functions of the Medical Department in combat are treatment and evacuation. These begin at the front line, where the company aid man gives the wounded soldier first aid and tags him for evacuation. He is then picked up by litter bearers and carried to the battalion aid station. This medical service must be continuous all the way from the front line to the zone of the interior.

The smallest unit to which medical officers are assigned in combat is the infantry battalion, an organization of about eight hundred men. Two medical officers are attached to a battalion at present, but owing to a shortage of medical manpower probably only one will be so assigned in the near future. This officer or officers, if there are two, establish a battalion aid station as near as possible in the rear of the battalion. Just how near this is depends on the terrain over which the unit is fighting. In rough country similar to Italy or in some types of jungle warfare the aid station may be in very close proximity to the fighting troops.

During the past two or three years the question of the waste of medical officers with tactical units has come up repeatedly. Why have a medical officer assigned to one of these tactical units when there seems to be so little medical work? Let me quote a statement from a returning battalion surgeon who has been in action: "The group that works in an aid station has to be extremely well trained to give immediate and proper care. Plasma injections quite often have to be given at the front line. There have been cases in our aid station in which, under very adverse conditions and with a lack of facilities, dangling arms or legs had to be amputated or packs of gauze inserted in gaping wounds to stop hemorrhages. All of this in a great number of instances necessitates well trained officers and Medical Corps men in sufficient numbers."

Backing up the medical service of the infantry battalions is the divisional medical battalion. The battalion is organized into collecting and clearing companies. The function of the collecting units is to evacuate the battalion aid stations to the clearing company either directly or through collection stations. In some instances casualties must be collected directly from the field, and in action involving armored units the area covered may be very

large. In some engagements ambulances and jeeps can come far forward, thereby reducing litter carry. In others, patients have to be carried for miles before they can be taken over by vehicles.

The clearing station of the medical battalion is established at a convenient site back of the front line, a distance averaging 4 to 7 miles. The clearing station not only acts as a hospital for the further treatment of the wounded but sorts out the various types of casualty.

The incidence of neuropsychiatric cases is in inverse proportion to the morale, and the cause starts right back here in the home territory. Soldiers' mail should not contain sentiments such as "I can't get along without you" or "When can you get home?" but should rather encourage him to get out and get the job done. Radio programs frequently carry the same note of nostalgic sentimentality, and this war has yet to produce a stimulating, stirring song such as has always been developed in past wars.

Relative to morale, a medical officer who has seen much active service in the present war states that "morale is directly in proportion to leadership; incidence of neuropsychiatric casualties is in inverse proportion to morale."

Clearing stations are evacuated by units of a higher echelon, either the corps or the army, and the patients are taken to evacuation hospitals. There are two types of evacuation hospitals, one having 400 and the other 750 beds.

Air evacuation has played a very important part in the transportation of wounded, both in the home territory and in theaters of operation. Recently large scale air evacuation made its debut in this country.

Medicine in the Navy

VICE ADMIRAL R. T. MCINTIRE: We have no right in medicine to make any plans at all on the finish of this war under three years. The medical department of the Navy is planning accordingly. We hope under the best of circumstances to see the European theater come to a climax in this coming fall. And we have a very tough job in the Pacific.

In the Navy we are laying our plans now to play a full part in the rehabilitation of our men. I know that the government has said that the Veterans Administration will be responsible for rehabilitation, and that is as it should be. But that will not excuse medicine in this country from doing its share. There will be a tremendous number of men who will come back from the wars to localities in which they hope to live and work. From now on to the end of this war, the man who comes into the service must be a man who can do full time duty. That is, he must be able to perform full duty in combat, because he will be a replacement. Thousands of men come back to us from combat areas. These men will never be fit for all duties again. Some will have lost an arm, some a leg, some one eye, some will have certain physical disabilities that will make them unfit for further combat. But those men are of great use to us in the service, and we are not going to send them on as useless. That is one of our first steps in rehabilitation. So our limited service group, then, becomes filled in a large extent by the man who has given his service in combat. When we bring him in his morale is raised, and the spirit that he brings for the men going on will pay us out over and over again.

We have interesting experimental work going on now in which certain industrial organizations are cooperating, where a man is being taught a trade, being taught a job while he is still in the hospital, taught by the organization into which he will go. The medical departments of both services are still saving lives; they are being saved in a heroic fashion by our men in the field. It would be a great comfort to the families in this country to know that, no matter where a man is in combat, very close to him is some member of the medical department. If he is unfortunate enough to be wounded, he has aid right at hand. It is a rare thing to see a man ever have to receive serious first aid from any other than a medical department representative. That goes for both services.

Then I can tell you some of the very tough things that these boys are doing—I am speaking of the enlisted men—in the services. We expect our doctors to be in there, and they are. But I can tell you that in one of the shows that just finished in Bougainville and Buin in certain sectors it would take twenty-four hours to move a casualty back 5 miles. Yet that was

being done hour after hour after hour, and being done so well by these men wading through the swamps and the jungles that our casualty figures somehow seemed to stay at about the same level. It speaks very well for those men who are working under such terrific conditions. Air transport comes into the picture in a much more prominent way than it did before, and we in the Navy will depend on it, for we are now out in the islands of the Pacific, and these islands are spread over tremendous distances. In fact, now we are likely to be fighting in a spot 700 or 800 miles from the nearest island that can support a large unit. We will need in the Pacific to evacuate these people directly to this spot, and that will be done. It means a great deal when one can do this.

I want to say that cooperation between the two services in all the theaters is excellent. I have thanked the Army for what it has done for us in Africa. The general hospitals have done a fine job for us. The reserve officers have done a magnificent job. They have gone into a foreign life. In peacetime the Navy has a rather set routine. We live in a very peculiar way. In wartime we haven't changed a great deal. When we bring a man into the group it's a little difficult for him to adjust himself. I have been astounded again and again when I see how well these reserve officers have functioned. It is not an uncommon thing for Captain Agnew to come in in the morning and say to me "I think so and so has done such a fine job that it will be well to give him a battleship" or we can put him on a heavy cruiser, or we can put him in this key job or that key job. And we are doing this. These men carry on for us. The regular officers simply form a skeleton for what is going on in our service.

I hope we can return to our set schedule of a yearly basis as far as medical school is concerned. I think we should, because fatigue is really something that comes on every one. I believe that year after year of nine month schedules with few breaks will do something to our professors and instructors. But pre-medical instruction is something else again.

Our research has still gone on, and we have developed two or three things that are very worth while. Our malaria control has advanced in splendid shape. We are now doing a much better job in the South Pacific. That takes time. We have two or three things that will save a lot of difficulty on board ship. Our research section developed a flash burn cream. That is sure to save a tremendous number of burns. To our research men in both the civil and military sides let me give a tremendous amount of credit for the hard work that they put in day after day.

The Expanding Field of Public Health and Preventive Medicine

SURGEON GENERAL THOMAS PARRAN, U. S. Public Health Service: The medical crisis has given us new tools and new methods which no thoughtful physician would wish to abandon and which will profoundly influence the practice of medicine and the national health for many decades to come. Important progress has been made in the attack on syphilis and gonorrhea. The sulfonamides and penicillin against gonorrhea, the new intensive therapy schedules and penicillin against syphilis—all these new tools have greatly shortened and simplified the treatment of these infections. The Public Health Service is currently operating a network of special treatment centers for the training of physicians, nurses and technicians and for the evaluation of the new short schedules. An extension of this type of special hospital is needed. The expansion of the mass tuberculosis case finding program, using the small film x-ray technic, has important implications both for medical education and for medicine. Reversing previous experience, 60 per cent of the cases uncovered in x-ray surveys are in the minimal reinfection stage as compared with approximately 10 per cent of the cases which came to treatment without intensive x-ray case finding. Formerly 90 per cent of the tuberculous patients were in need of hospitalization by the time a diagnosis was made. Improvement in methods of treatment now make it possible for the majority of patients in the early stages to be treated successfully without hospital care. Through hard necessity we have proved the value of new technics for the control of the venereal diseases, tuberculosis and malaria. We have learned much in the construction and operation of community hospital health centers. Preventive industrial medicine has been more widely

applied during the past three years than at any other time in our history. And the groundwork has been laid for national and worldwide nutrition programs. Preventive measures are indistinguishable from what has always been thought of as "curative." The same is true in the prevention of war psychoses. We have made definite progress in five important public health areas during the war. Each of these lines of action has been directed against a critical wartime problem. Each of these problems had been defined and redefined, and proposals made for their solution before the war. The results of our efforts during the war are sufficiently encouraging to suggest that these programs should be expanded now and projected into the post-war period with increasing momentum.

Before the war many urban areas in the United States lacked adequate safe water supplies, sewage disposal systems and other sanitary facilities. The war intensified these needs and created new demands in areas where large military and industrial installations were constructed. Through the provisions of the Lanham act only the most urgent of these needs have been met, and our public health engineers estimate that it will take an expenditure of about \$300 million annually for ten years to correct present deficiencies in sanitation facilities of all types. Even more acute has been the shortage of hospitals and health centers. To date, under the Lanham act, hospitals with a total bed capacity of about 10,000 have been constructed or converted. Health centers designed to house the local health department as well as clinical and diagnostic facilities have been constructed in a number of communities. The provision in Federal Public Housing projects of infirmaries, health centers and office quarters for private physicians has also helped to alleviate the shortage of health and medical facilities in war industrial areas.

Persistent malaria control work in the Southern states during the past decade has borne fruit. The trend is now sharply downward in this disease, which has been one of the South's heaviest health and economic burdens. Intensification of the work around Southern military and war industrial establishments has made it possible to increase our gains against malaria.

The expansion of industrial hygiene services and industrial medicine during the war has been one of the most significant advances in public health. Yet the shortage of trained personnel in this field—so intimately related to the needs of our industrial civilization—has precluded full application of available knowledge for the prevention of occupational diseases and the promotion of the worker's health. Plans for reconversion and full peacetime production indicate that the opportunities for medicine in the field of industrial hygiene will continue and increase in proportion to the availability of competent personnel.

Attempts to alleviate the overall acute medical shortage in civilian areas have not proved entirely successful. Closely linked as this problem is with the prewar maldistribution of physicians, it is not likely that the situation will definitely improve for the duration. Better distribution of medical manpower must be the first order of business in the evolution of any national health program projected for the future. We shall need a considerable increase in trained public health personnel to achieve the goal of adequate health services in all parts of the country. This will overtax the facilities of existing public health schools. There are large rural areas in which the level of public health and medical practice may be raised by the closer integration of private practice with public health service. In such areas the ideal would be to have every private practitioner devote a part of his time to community health service. To attain this ideal our medical schools will need to produce more general practitioners for our postwar society—well trained in both preventive and curative medicine, with a knowledge of modern psychiatry and nutrition, with access to a good hospital. The economic risk to the physician who elects to practice in a low income area is great. Some means should be found to underwrite the risk as well as to provide the facilities, for we need to attract the highest type of our younger men if we are to sustain good community medical and health services.

Present indications are that public health is at the beginning of a new era—an era of positive advance in which the goals will be higher levels of health rather than solely the control of epidemic diseases. Ever a field of increasing returns, public health practice, however, will attain the new goals only as it advances in dynamic union with medical practice. And, con-

versely, progress in medical practice depends on the application of new knowledge on the broad scale implicit in the modern concept of public health. Such a united advance is predicated on the past performance and future achievements of our medical schools and boards of licensure.

The Army Specialized Training Program

COLONEL FRANCIS M. FITTS, M. C., A. U. S.: There are now 23,360 enlisted men of the Army assigned to Army Service Forces units at 124 approved schools of medicine, dentistry and veterinary medicine, and at 51 colleges and universities accredited for premedical, predental and preveterinary instruction. These enlisted men have been assigned to these units for the definite and special military duty of preparing themselves, under the Army Specialized Training Program, for the appropriate doctor's degree in order that they may be commissioned in the Army of the United States as replacements for the expected losses among medical, dental and veterinary officers. This figure represents 13,680 enlisted men detailed for the study of medicine, 5,761 for that of dentistry and 1,392 under instruction in veterinary medicine; 2,527 are in AST units in preparation for assignment for professional training in these three fields. Unless the requirements of the Surgeon General for loss replacements are modified, the number of trainees studying medicine should remain fairly constant and will require the utilization of 55 per cent of the capacity of the approved schools of medicine in the United States. The number under training in dentistry will gradually decrease to 35 per cent of the capacity of the dental schools, i. e. to about 3,700. Training in veterinary medicine will be discontinued when the present trainees have been graduated. Enlisted men in preprofessional curriculums under preparation for assignment to 1945 vacancies will increase each month to about 5,500 by October 1944 and remain at that level.

The first army selected and army trained preprofessional trainees will be assigned to AST units at medical and dental schools in January 1945. Thereafter, during each nine months' period, we must so assign 3,500 enlisted men qualified for the study of medicine and 1,040 for that of dentistry. Since the vacancies in professional schools recur at irregular intervals, provisions must necessarily be made for the interim duties between the completion of preprofessional and the beginning of professional training. Such interim duties will be in Army Service Forces installations and with the Medical Department. Training in medicine and dentistry is thirty-six months in length and follows the standard curriculum of each contracting school. On receipt of the degree of doctor of medicine or dentistry the trainee will be discharged from his enlisted status in order to accept a commission in the Medical or Dental Corps, Army of the United States. The newly appointed dental officer will be ordered to active duty on appointment. Active duty, however, for medical officers will be delayed a minimum of nine months for the completion, on an inactive status, of the prescribed hospital internship. Graduates in veterinary medicine will be appointed in the Veterinary Corps in such numbers as the military situation requires. Those not commissioned will be discharged to meet the requirements of the nation's animal industry.

Briefly, this is the Army Specialized Training Professional and Preprofessional Program. Every attempt has been made to continue the training of medical and dental students and to provide physicians and dentists for the military forces with the minimum interruption of scheduled instruction and the minimum changes in curriculums. As a result there have been numerous and frequently confusing modifications of the standard procedures of classification for and assignment to the Army Specialized Training Program. However, I am sure that it is quite apparent that the potential doctors and dentists, destined as medical and dental officers of the Army, cannot be chosen on purely quantitative qualifications and without regard to sincere interest in and aptitude and fitness for the study of a chosen profession. Careful screening procedures are necessary in order that the attrition in this lengthy—and costly—program be kept at a minimum and that the production of the highest type of physician and dentist for the Army be assured.

The wide departure from past experience in the selection of medical and dental students, the reduction in the period of premedical and predental preparation and the anonymous assign-

ment of trainees to individual schools of medicine and dentistry constitute a challenge to the Army's training program. The standards of medical and dental education must not be lowered. They may be maintained without undue attrition among the enlisted trainees only if their selection, preparation and application under the Army Specialized Training Program are superior. Our administrative procedures must be directed toward this end. I am confident that the scholastic competence of ASTP trainees assigned for preprofessional and for professional training will be the equal of, if not, as I firmly believe, superior to that of those who have entered on the study of medicine and dentistry in previous years. The availability of enlisted men who are sincerely interested in professional studies and possess the desired aptitude and fitness for medicine and dentistry will depend largely on the number of trainees in the basic curriculum. Both quantity and quality must be maintained. There is much at stake in the Army and in civil life after the war.

Medical Manpower for Civilians

DR. HARVEY B. STONE, Vice Chairman, Directing Board, Procurement and Assignment Service for Physicians: The Procurement and Assignment Service has been acting as a clearing house for the various interests that require the services of medical personnel, seeking to distribute a strictly limited supply as widely and fairly as possible to meet a greatly increased and varied demand. The first and most urgent of these demands has been the requirements of the federal services, but we were enjoined in our Presidential authorization to do this "with due regard for civilian needs." It has been agreed that the ratio of 1 practicing physician to 1,500 people is a minimum adequate provision. With this as a basis of calculation, it was then determined how many doctors could be withdrawn from civilian practice for federal service. The full number of officers allocated to the federal services has not yet been actually provided to them. There are still several thousand doctors marked available for such service who for various reasons have not been commissioned. This occasion cannot be lost to urge that the men considered available be induced to accept commissions. Of primary importance is the maintenance of medical educators so that a continuing and increased supply of well trained doctors may be produced. The staffs of the schools have been seriously reduced, the number of students increased and the curriculum accelerated. In consequence, a situation has been reached in which authoritative voices have warned that no further withdrawals from faculties of medicine can safely be made. Similarly the hospitals must be allowed to keep enough interns and residents to render safe and adequate care to their patients. The group of doctors concerned here, the most recent graduates, is precisely the group that the armed forces regard as most useful to themselves and that they therefore are most desirous of commissioning. The difficulty of the situation is increased by the fact that even in peacetime there were more approved internships available than there were graduates each year in medicine.

These considerations led to the adoption of two plans designed to effect a working solution of the conflicts of interests and demands. These two plans are known as the 9-9-9 intern-resident program and the hospital quota program. The 9-9-9 plan, so far as it relates to the period of appointments of hospital personnel, applies to all alike, whether militarized or not. This is obviously necessary for uniformity of time periods of all appointments. As far as it limits the appointment of a man to one period each as intern, assistant resident and resident, it applies only to militarized personnel. Others may be continued on the house staff as long as the hospital desires. This provides an opportunity for prolonged training of individuals not subject to military orders. On the other hand the quota allowed each hospital includes both military and nonmilitary house officers.

A fairly accurate and complete picture of medical personnel needs of the whole country has been kept current. At the same time certain groups, particularly the field force of the Procurement and Assignment Service, have been on the alert to find and persuade doctors to relocate. Also communities have been stimulated to make relocation attractive by arranging for living and office quarters. State licensing boards have been cooperative in easing the legal difficulties of men moving across state lines. Well over two thousand locations have been accomplished up to the present.

The Procurement and Assignment Service has been concerned with and had a part in the provision of medical personnel for industry and for the new communities that have sprung up in various parts of the country. Its plan of action here has been parallel to that described for other civilian needs and has perhaps been equally successful. Problems have been presented to us by the Veterans Bureau and by other federal agencies and by special situations that have arisen. New problems will undoubtedly arise with the end of the war and demobilization. What part, if any, the Procurement and Assignment Service will be called on to play in these anticipated developments is as yet undetermined.

Wartime Graduate Training

CAPTAIN EDWARD L. BORTZ (MC), U.S.N.R.: Graduate medical education, residencies and fellowships, together with the activities of the specialty boards, have been important influences in bringing medicine to its present high level in the United States, as emphasized by Balfour. The formalized course of the residency and the fellowship, essential for young teachers in peacetime, may readily be modified in the presence of a national emergency so that prospective teachers may enter military service. While participating in the military program they may obtain a quality of experience that will be of invaluable assistance in later years. It is significant that certifying boards are granting credits to doctors in service today who are doing work at a graduate level in anticipation of taking the examinations for certification.

To maintain the quality of teaching that has produced the present high standard of medical education, it is essential that sufficient provision be made for a continuous flow of teaching personnel. Thoughtful observers have suggested that teachers from the various medical school faculties now in service should be returned to teaching after a period of experience with the troops, exchanging places with colleagues who have remained in a civilian capacity.

First hand experience in the theaters of war has emphasized the necessity of specialized training for medical officers. Large numbers of them have been given advanced instruction in certain of the major subjects at various medical centers here and abroad. Courses have been given in epidemiology, laboratory medicine, tropical diseases, venereal disease, radiology, physical therapy, aviation medicine, general and specialized branches of surgery, anesthesia, problems of transfusion, plasma, the treatment of shock and so on. Through these courses medical officers are receiving instruction under the direction of qualified experts in the various specialties which would have been impossible in peacetime. This training, however, is not expected to develop specialists. It is an important means of better fitting the doctors to cope with many of the war casualties.

In addition to the many researches being carried on in some of the large installations, service staff doctors regularly hold medical conferences, staff meetings, teaching ward rounds and special demonstrations; likewise a large number of instructive motion pictures dealing with current problems are available for teaching. Service hospitals adjacent to medical schools might well play an important role in the clinical instruction of medical students, since clinical material and teaching personnel of the highest standards are available. Not infrequently, service doctors are invited to address classes in medical schools; likewise, faculty members from the various schools visit the service hospitals and participate in programs of instruction.

Through the Office of Scientific Research and Development, authorities from the three services are in constant contact with the topflight investigators of the various medical schools. At no other time in the history of our country has there been greater medical research activity than is being carried on now.

Under the auspices of the American Medical Association, the American College of Physicians and the American College of Surgeons, and with the authorization of the three surgeons general, a significant extensive movement in medical education has been carried on for the past year. Originally tried out on a small scale by the American College of Physicians, groups of teachers from medical schools were organized for the purpose of conducting periods of instruction in a certain number of service hospitals. These events were so cordially received, and the service doctors were so eager to have them repeated, that a

nationwide movement was organized, under the stimulus and guidance of the three major medical organizations. With the authorization of the three surgeons general, who have been most generous in their support, and aided by the deans and faculties of some fifty medical schools, meetings in the form of teaching ward rounds, clinical pathologic conferences, study groups, question and answer periods, moving pictures and other types of practical demonstrations have been presented throughout the entire nation. The subjects most frequently presented were (1) chemotherapy, (2) cardiovascular diseases, (3) gastrointestinal disorders, (4) general surgery, (5) psychiatry, (6) malaria, (7) rheumatism and arthritis, (8) orthopedic surgery, (9) shock, burns, blood substitutes and (10) (a) neurosurgery, (b) traumatic surgery of the abdomen and chest.

Many of the larger medical installations have their own clinical conferences and study groups. Where such programs have already been instituted, the role of the Wartime Graduate Medical Meetings has been twofold: (1) meetings have been jointly planned and conducted by the service hospital authorities and the regional committee of the Wartime Graduate Medical Meetings; (2) lecturers have been invited, through Wartime Graduate Medical Meetings, to participate in meetings planned by the service hospital staff. The objective is continuous graduate education to meet the needs and desires of physicians in the armed forces as well as those in civilian practice.

The majority of doctors are unable, for one reason or another, to take one, two or three years off for special training. For these members of medicine, who study the literature and who are eager for the stimulus that is derived from intimate contact with nationally-known authorities at regular intervals, the short brush up course has proved a helpful instrument. This type of course is not a short cut to a specialty. It does not produce specialists. It represents one of several helpful aids to a higher brand of medical practice for many doctors who can arrange for one or more weeks to be profitably spent following a master clinician or teacher as he goes on rounds or conducts a conference or seminar. Courses on special subjects have been successfully conducted by the Army, the Navy, the Public Health Service, the American College of Physicians and the American College of Surgeons. Furthermore, many other organizations have offered attractive teaching programs for small groups, all of which have played a role in elevating the plane of medical practice.

When hostilities cease, presumably the majority of doctors will return to practice and hospital duties. Many of these men are anticipating courses, from time to time, of two, four, six or eight weeks during which they may be given the privilege of a thorough review of recent work in various fields. Even during wartime such courses have constantly been in demand. With assistance from deans and faculties of the medical schools, such courses can be arranged throughout the nation. When scheduled on a peacetime basis, it may be possible for a man to spend two to four weeks at one school and, if time permits, move on to another school for a course in a different field. Military medicine as a career will attract an increasing number of young graduates. There needs to be a closer rapprochement between the medical services of the armed forces and the sources of supply for trained personnel.

(To be continued)

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at 4:30 p. m. Eastern war time (3:30 Central war time, 2:30 Mountain war time and 1:30 Pacific war time).

The titles and guest speakers for the next three programs are as follows:

March 25. "Our Blood for Our Boys."

Speaker, Harold A. Vonachen, M.D., medical director, Caterpillar Tractor Company, Peoria, Ill.

April 1. "White Reaper."

Speaker, Kendall Emerson, M.D., managing director, National Tuberculosis Association, New York.

April 8. "Men with New Faces."

Speaker, Major General D. N. W. Grant, M. C., A. U. S. Air Surgeon, A. A. F., Washington, D. C.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 1250 has been reported to the House of Representatives, proposing to repeal the existing law which provides for the forfeiture of pay of persons in the military and naval service of the United States who are absent from duty on account of the direct effects of venereal diseases due to misconduct. H. R. 2985 has passed the House, providing for the garnishment, execution or trustees process of wages and salaries of civil officers and employees of the United States. H. R. 4346 has passed the House, making appropriations to supply deficiencies and to provide supplemental appropriations for the fiscal year ending June 30, 1944. Among other things, the bill appropriates an additional \$2,700,000 for the nurses' training program, an additional \$127,500,000 for the construction of community facilities, including hospitals, and \$30,000,000 for the construction of 9,252 additional beds for veterans' facilities: 100 beds for the tuberculous, 100 general beds (cancer cases) and 9,052 beds for neuropsychiatric patients.

Bills Introduced.—S. 1767, introduced by Senator Clark, Missouri, for himself and seventy-eight other senators, proposes to provide federal aid for the readjustment in civilian life of returning World War II veterans. This bill, to be cited as the "Servicemen's Aid Act of 1944," declares the Veterans' Administration to be an agency of the United States vital and essential to the successful prosecution of the war and entitled to priorities second only to the War and Navy Departments; directs the Administrator of Veterans' Affairs and the Federal Board of Hospitalization to expedite the construction of additional hospital facilities for war veterans and to enter into agreements and contracts for the use of suitable Army and Navy hospitals by the Veterans' Administration after cessation of hostilities and after such institutions are no longer needed by the armed services; appropriates \$500,000,000 for the construction of additional hospital facilities; authorizes the Administrator of Veterans' Affairs and the Secretary of War and the Secretary of the Navy to enter into agreements for the mutual use or exchange of use of hospital and domiciliary facilities; provides for the transfer or detail of commissioned or enlisted personnel from the armed forces to the Veterans' Administration and provides for the postwar education and training of any person who served in the active military or naval service on or after Sept. 16, 1940 and prior to the termination of the present war and whose education or training was interrupted or prevented by service or who requires a refresher or retraining course to fit him for employment or profession. This bill is pending in the Senate Committee on Finance. A companion bill, H. R. 4357, introduced by Representative Rankin, Mississippi, is pending in the House Committee on World War Veterans' Legislation. S. 1781, introduced by Senator Johnson, Colorado, provides for full military rank for members of the Army Nurse Corps, dietitians and physical therapy aides. H. R. 4351, introduced by Representative Lane, Massachusetts, provides retirement benefits for emergency officers of World War I who heretofore have failed to apply for the benefits within the time prescribed by existing law. H. R. 4369, introduced by Representative Fish, New York, proposes an appropriation of \$5,000,000 to enable the Administrator of Veterans' Affairs to provide seeing-eye dogs for blind veterans who are entitled to disability compensation under the laws administered by the administrator.

STATE MEDICAL LEGISLATION

Arizona

Bills Introduced.—H. 18-XX proposes that the annual registration fee required of osteopaths be reduced to \$6 for the fiscal year ending June 30, 1945. H. 20-XX proposes that the annual registration fee required of naturopaths be reduced to \$5 for the same period. H. 23-XX proposes that the annual registration fee required of chiropractors for that period also be reduced to \$5. H. 24-XX proposes that the annual registration fee for the fiscal year ending June 30, 1945 with respect to licentiates of the medical practice act be reduced to \$150. H. 28-XX proposes to exempt from the payment of the annual

registration fee required by law from practitioners of professions and businesses any member of the armed forces of the United States, a citizen of the state, who at the time of his induction into the armed services held a valid and subsisting license from the state.

Mississippi

Bill Introduced.—H. 791 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate that the party has been examined for the presence of a venereal disease.

New Jersey

Bills Introduced.—S. 152, to amend the law relating to medical service corporations, proposes, it would seem, to permit a medical service corporation, other than a medical service corporation organized without capital stock and not for profit, to establish, maintain and operate medical service plans. A 309 proposes to repeal the present medical practice act.

New York

Bills Introduced.—S. 1550 and A. 1957 propose to require every physician attending or a hospital caring for a case of a wound inflicted by a pointed instrument to report the facts at once to appropriate police authorities. Under the present law such a report is required in cases of injuries arising from or caused by the discharge of a firearm, which will no longer be required if either of these bills, is enacted. S. 1572 and A. 1972 propose to authorize the revocation or suspension of the license of any qualified examiner or qualified psychologist for a violation of the mental hygiene law or any law in the course of the practice of his vocation or for fraudulent or dishonest practice or incompetence or untrustworthiness.

Bill Passed.—S. 1489, to amend the uniform narcotic drug act, passed the senate March 13. This bill proposes so to define narcotic drugs as to include isonipheccaine, which the bill states "means the substance identified chemically as 1-methyl-4-phenyl-piperidine-4-carboxylic acid ethyl ester, or any salt thereof by whatever trade name identified."

Rhode Island

Bills Introduced.—H. 784 proposes to enact a separate naturopathic practice act and to authorize the director of health, with the approval of the governor, to appoint a board of three examiners in naturopathy to examine and license applicants for licenses to practice naturopathy. The bill proposes that "the practice of the profession of naturopathy is hereby designated as drugless and nonmedical and is defined as a science dealing with the diagnosis and treatment of disease through natural therapeutics. It shall embrace and include physiological, anatomical and dietetic sciences, such as physiotherapy, dietetics and the use of herbs, including foods, powdered and dehydrated, and fruits, and such other methods of treatment as are taught in the various recognized schools of naturopathy, except the practice of major surgery and the prescription of drugs." H. 825 proposes to direct the director of education to arrange for annual lectures to be given to the students of each high school of the state explaining the problems of cancer and the means for its cure and control. H. 879 proposes to permit a licensed chiropodist or podiatrist to prescribe, purchase, administer and dispense narcotic drugs in good faith and in the course of his professional practice only. H. 833 proposes to require every city and town to make provisions for a school health program, including health service, health instruction and physical education, under such rules and regulations as may be promulgated by the state director of education in cooperation with the state director of health.

South Carolina

Bill Introduced.—S. 963, to amend the laws relating to the practice of osteopathy, proposes to make eligible for examination and licensure a graduate of an approved osteopathic college "if he or she has attended four full courses of lectures of at least thirty-six (36) weeks each, or any combination of such courses aggregating one hundred forty-four (144) weeks and has received a diploma therefrom."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Physician Observes Ninety-Third Birthday.—On February 1 Dr. William J. Curry, Rogers, observed his 93d birthday. Newspapers reported that Dr. Curry kept office hours as usual and attended to patients.

District Meeting.—The First Councilor District Medical Society of northeast Arkansas was addressed in Jonesboro, March 22, by Drs. Eugene M. Holder, Memphis, Tenn., on acute surgical conditions of the abdomen and Dr. Percy S. Pelouze, Philadelphia, on gonorrhea.

CALIFORNIA

Dr. Alton Ochsner Lectures.—Dr. Alton Ochsner, William Henderson professor of surgery, Tulane University of Louisiana School of Medicine, New Orleans, will give a series of lectures in San Jose, April 3-8, under the auspices of the San Jose Hospital staff. Dr. Ochsner will, in his discussion, cover gallbladder disease and its surgery, bronchogenic carcinoma, preoperative and postoperative care and diseases of the peripheral vascular system. He will also deliver a public lecture on the control of cancer. Interested physicians are invited to attend the lectures.

The Charles Cook Hastings Home for Tuberculosis.—Preparations are now under way to establish the Charles Cook Hastings Home on a 7 acre tract of land purchased from the La Vina Sanatorium, La Vina, near Pasadena (THE JOURNAL, May 23, 1942, p. 356). The establishment of the home was provided for in the will of the late Charles H. Hastings in memory of his father. The project will be financed and directed by the Hastings Foundation, which was also set up in the will for research into the cause and cure of tuberculosis and other diseases. The foundation was organized Feb. 19, 1943. Under the recent agreement Dr. Carl Howson, Los Angeles, medical director of the La Vina Sanatorium, will become first medical director of the Charles Cook Hastings Home. The project will begin operations by conducting research into the causes and possible means of curing tuberculosis and provide care and treatment for from 16 to 20 persons afflicted with tuberculosis. The patients of the home shall be cared for free from all costs and charges of any kind. It is hoped that construction may be begun in the spring, contingent on obtaining the necessary priorities.

CONNECTICUT

Personal.—Dr. Roy M. Seideman, formerly of Rochester, N. Y., has been appointed industrial hygiene physician in the bureau of industrial hygiene of the Connecticut State Department of Health, Hartford.

Health Consultant Needed.—The state personnel department of Connecticut announces an open competitive examination for the position of local health consultant, the last date for filing application to be April 8. Applicants must have not less than five years' employment in public health work, including experience as health officer of a municipality, county or district; or completion of postgraduate training in public health work in three years of such experience; or an equivalent combination of experience and training. The applicant must be eligible for a license to practice medicine and surgery in Connecticut. Connecticut residence is waived for the examination, but candidates must be citizens of the United States. The salary range is \$5,100 to \$5,700 a year. Additional information may be obtained from the personnel department, State of Connecticut, State Capitol, Hartford.

DISTRICT OF COLUMBIA

Dr. Bocock Heads Medical Center.—Dr. Edgar A. Bocock, until recently head of Gallinger Municipal Hospital, has been named administrator of Doctors Hospital and superintendent of the Medical Center, including the hospital and the adjoining Washington and Columbia medical building. The committee that selected Dr. Bocock was headed by Dr. Charles Stanley White, president of the four corporations that own the medical center. Doctors Hospital is four years old.

FLORIDA

Temporary Licensing of Relocated Physicians.—Under executive order, the governor recently directed the state defense council to license during the war emergency relocated physicians in particular counties with certain stipulations. These licenses may be granted if the council receives:

A certificate of need for such a physician from the county medical society, or, in the absence of a county medical society, a certificate to such effect from the board of governors of the Florida Medical Association. Such certificate must give the name of the physician, the state in which he last practiced, the fact that he was in good standing in that state and a statement that his educational qualifications meet the state requirement. Such certificate must be approved by the state office of medical procurement and assignment service.

A certificate from the state board of medical examiners approving the procedure for the temporary licensing of relocated physicians.

A certificate from the state board of health approving the procedure for temporary licensing of relocated physicians.

A resolution from the board of governors of the Florida Medical Association approving the procedure.

A resolution of the state defense council issuing the license to the physician certified to practice in a particular county only, subject to the same laws and regulations as other physicians, his license subject to revocation by operation of law or by direction of the governor; but in no event shall the license continue in effect longer than six months after the end of World War II.

INDIANA

Plaque Honors Dr. Barnhill.—A scholarship plaque has been established by the Indiana University chapter of Phi Delta Epsilon medical fraternity as a memorial to the late Dr. John F. Barnhill, Indianapolis, who had been a member of the faculty of the university for thirty-eight years. The plaque will be placed in the medical building on the Bloomington campus. The Indiana chapter of the fraternity has also offered to defray the expense of an annual address at the medical school by a prominent anatomist. The address would be given in connection with an inscription on the plaque of the name of the student achieving the highest scholarship in gross anatomy.

KANSAS

Course on Medical Protozoology.—A short course on medical protozoology was held at the University of Kansas, Lawrence, February 28-March 4. It included preliminary work in malaria, Trypanosoma and Leishmania, Endamoeba histolytica, amebas, intestinal flagellates of man, intestinal ciliates and sporozoa. Miss Mary E. Larson, assistant professor of zoology, University of Kansas, conducted the course.

Snyder Memorial Foundation.—The Snyder Memorial Foundation was recently granted a charter to act in the "investigation of and the research concerning the problems of medicine and surgery, and the dissemination of knowledge thus acquired . . . also for the advancement of medicine and surgery. . . ." The new foundation was named in honor of the late Dr. Howard L. Snyder, Winfield, who died Aug. 16, 1940. He was president of the state society, 1936-1937. The foundation is a nonprofit group organized and registered on Nov. 8, 1943. Its charter was filed by Mr. Walton Goode with offices at 103½ East Ninth Street, Winfield, where the offices of the new corporation will also be located. It is sponsored by Mr. A. W. Kincaide, Wichita; Major Howard E. Snyder, M. R. C., and Dr. Cecil D. Snyder, Winfield, sons of Dr. Snyder; Dr. Harold H. Jones, Winfield, and Mr. Goode.

LOUISIANA

Health Department Moves.—All of the city health departments except the laboratories have moved from the present headquarters in the city hall to the old Poydras Building, on the corner of Poydras and Carondelet streets. The ground floor of the building will be used for various phases of the work on vital statistics, according to the *Bulletin* of the Orleans Parish Medical Society.

Medical Society Urges Action on Insurance Bill.—The Orleans Parish Medical Society recently adopted a resolution recommending the immediate passage of the pending Bailey-Van Nuys bill, which excludes fire insurance companies from the provisions of the antitrust laws, on the basis that opposition to this bill "constitutes a vigorous attempt to deprive the respective states of the right to regulate the insurance companies and to center the authority in Washington."

Appointments to Tulane.—Dr. Cecil A. Krakower, formerly connected with the Columbia University School of Tropical Medicine in San Juan, P. R., has been appointed assistant professor of bacteriology and pathology at Tulane University of Louisiana School of Medicine, New Orleans. Dr. Arthur Judson Walker, formerly acting medical director of the Firestone Plantations Company in Liberia, has been named assistant professor of tropical medicine at the school.

Hospital News.—Charity Hospital, New Orleans, recently acquired an extensive area, the hospital board has approved its use in selected private cases though its control remains with Charity Hospital.—The Eye, Ear, Nose and Throat Hospital, New Orleans, has been made a residuary legatee of the estate of the late Mrs. Celeste Stauffer Eastwick, a former resident of New Orleans who recently died in New York. The exact amount of the bequest is unknown, but it is believed that it will be sufficient for the erection and operation of additional hospital facilities. Additional funds will revert to the institution on the death of Mrs. Eastwick's heirs.

MARYLAND

The Thayer Lectures.—Dr. Richard E. Shope, a member of the Rockefeller Institute for Medical Research in the department of animal and plant pathology, Princeton, N. J., commander in the U. S. Naval Reserve, delivered the fourteenth course of lectures under the William Sydney Thayer and Susan Read Thayer lectureship in clinical medicine, March 16-17, at Hurd Memorial Hall, Johns Hopkins Hospital, Baltimore. His subject was "Old, Intermediate and Contemporary Contributions to Our Knowledge of Pandemic Influenza."

Personal.—Dr. Elvin L. Sederlin, Bismarck, has resigned as acting director of the venereal disease control division of the North Dakota state health department in order to accept a position as assistant health director of Baltimore County.—Dr. James A. McCallum, Centerville, health officer of Queen Annes County, has been appointed health officer of Washington County, succeeding Dr. William R. Willard, Hagerstown.—Dr. Harry B. Smith, formerly of Jacksonville, Fla., and now field consultant in the division of venereal disease control in the state department of health, has been appointed senior medical supervisor in the bureau of venereal disease of the Baltimore City Department of Health.

Meeting on Shock.—The pathologic section of the Baltimore City Medical Society sponsored a meeting March 3 at which Dr. Virgil H. Moon, professor of pathology, Jefferson Medical College of Philadelphia, spoke on "The Mechanisms of Shock as Related to Clinical Management." In a discussion of the principal paper Dr. Alfred Blalock, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, presented the differences of opinion on the subject; Dr. Harry N. Harkins, associate professor of surgery at Johns Hopkins, the need for collaboration between the several schools of thought, and William R. Amberson, Ph.D., professor of physiology, University of Maryland School of Medicine and College of Physicians and Surgeons, the need for continued investigation in the use of pure hemoglobin in the therapy of shock.

MASSACHUSETTS

Dr. Emerson Retires After Thirty-Five Years in State Service.—Dr. Ernest B. Emerson, for twenty-six years superintendent of the Rutland State Sanatorium, Rutland, has retired, ending almost thirty-five years in state service. Dr. Emerson graduated at Harvard University Medical School, Boston, in 1898.

Dr. Avery Goes to Iran.—Dr. Bennett F. Avery has resigned as dean of Boston University School of Medicine to accept an appointment as director general of public health of Iran. Dr. Avery, who graduated at the University of Michigan Medical School, Ann Arbor, in 1925, spent considerable time at the American University of Beirut, Beirut, Syria, serving as adjunct professor of anatomy and later as associate professor. He also served for a time as acting dean.

MICHIGAN

Physician's Death Involves Murder Charge in Riot Trial.—On March 15 Aaron Fox, Detroit, was sentenced to serve from seven and one-half to twenty-five years in prison for second degree murder in connection with the race riot slaying in June 1943 of Dr. Joseph De Horatiis. Newspapers report that the arrest warrant accused Fox of hurling a brick through the window of the physician's car and hitting him on the head.

MINNESOTA

State Medical Meeting.—The Minnesota State Medical Association will hold its ninety-first annual meeting at the Mayo Civic Auditorium, Rochester, April 13-15, under the presidency of Dr. Elmer M. Jones, St. Paul. Dr. Ralph S. Bromer, Bryn Mawr, Pa., will deliver the Russell D. Carman Memorial Lecture, April 13, on "Roentgenologic Diagnosis of Skeletal Disease in Infants and Children." Other guest speakers who will make their appearance under special auspices include Drs. Ralph M. Waters, Madison, Wis., Northern

Minnesota Medical Association, on "Summary and General Considerations of Anesthesia in General Practice," and Hugh McCulloch, St. Louis, Northwestern Pediatrics Society, on "Significance of Rheumatic Fever to the Community." Other guest speakers on the program include:

Vice Admiral Ross T. McIntire, surgeon general of the U. S. Navy, Tropical Diseases.
Dr. Raymond W. McNealy, Chicago, Summary and Discussion of Pre-operative and Postoperative Care for the Bad Risk Patient.
Dr. John H. Moore, Grand Forks, N. D., Responsibility of the Physician in Obstetric Practice.
Dr. Ralph A. Reis, Chicago, Control of Obstetric Hemorrhage.

Other speakers on the program include the following physicians: Drs. Herbert P. Johnson, Rochester, on "Clinical Application of Cover Test and Prism Screening"; Frederick A. Figi, Rochester, "Malignant Tumors of the Middle Ear and Mastoid," and Ernest M. Hammes, Rochester, "Differential Diagnosis of Choked Disk and Optic Neuritis." Sessions will be held on peptic ulcer, anesthesia in general practice, chemotherapy, preoperative and postoperative care for the bad risk patient, current problems in obstetric practice, orthopedic and fracture surgery, diseases of the colon and diseases of the chest. One session will be devoted to a series of case reports and another to a series of round table luncheons. The Olmsted-Houston-Fillmore-Dodge County Medical Society and the state medical association will hold an open house, April 13, in the Mayo Civic Auditorium Arena and Theater. Dr. Herman L. Kretschmer, Chicago, President-Elect of the American Medical Association, will be guest on this occasion. Other features of the meeting will be the presentation of the medal awarded annually by the Southern Minnesota Medical Association for the best scientific exhibit and the presentation of certificates to candidates of the "Fifty Club," who have practiced medicine for fifty years.

NEW YORK

Time Between Tuberculosis Reporting and Death.—*Health News* reports that a recent study of tuberculosis case reporting in upstate New York disclosed that during the years 1940-1942 about 21 per cent of the fatalities from all forms of tuberculosis were not reported as cases before death. In addition, about 17 per cent of the total were reported within less than three months before death and another 6 per cent within three to six months before death. In other words, it was pointed out, about 44 per cent of the deaths either were not reported at all during life or were reported a relatively short time before death. In explaining circumstances which extenuated this situation, *Health News* states that in certain instances, for example, tuberculosis, the diagnosis is based only on the necropsy. In others the deaths are from nonpulmonary forms of the disease, in which there is ordinarily no exposure hazard. Some deaths occur in persons who establish residence in upstate New York a short time before death. Other similar factors may account for some of the late reporting but they explain only a small proportion, it was stated.

New York City

Personal.—Frank S. Lloyd, Ph.D., executive director of the physical fitness division of the Federal Security Agency and professor of education at the New York University, has been appointed chairman of the hygiene department of College of the City of New York, to succeed Frederic A. Woll, Ph.D., who in June will reach the mandatory retirement age of 70.

Dr. James Shannon to Head Department of Pharmacology.—Dr. James A. Shannon, associate professor of medicine at New York University College of Medicine since 1942, will become professor and chairman of the department of pharmacology at the university on the retirement next September of Dr. George B. Wallace. Dr. Shannon graduated from the university in 1929. He has written extensively on renal physiology and is currently devoting all his time to the development of more effective means for the suppression and treatment of malaria under the auspices of the Office of Scientific Research and Development.

Medical Society Protests Compensation Charges.—The Medical Society of the County of New York has protested to Governor Dewey that "serious accusations and innuendoes" contained in a report of administration of the state workmen's compensation law are "biased and untrue." Newspapers stated that the report charged defrauding of injured workers in compensation cases. The governor was asked to furnish to the society a copy of the report, so that he might receive "the facts in refutation of accusations made against medical societies" and to enable the governor "to recommend proper legislation after review of the facts." The society told the governor that it was mailing to him a copy of resolutions adopted February 28, in which recommendations for amendments to the workmen's compensation law were made.

Research Council Chooses Officers.—Dr. Willard C. Rappleye, dean of the Columbia University College of Physicians and Surgeons, on March 8 was reelected chairman of the research council of the Department of Hospitals of the City of New York. Dr. Edward M. Bernecker, commissioner of hospitals, was reelected vice chairman. Other officers include Dr. Alfred E. Cohn of the Rockefeller Institute for Medical Research, treasurer, and Dr. Walter G. Lough, president of the medical board of Goldwater Memorial Hospital, secretary. The council of the Department of Hospitals was set up in 1935 by the late Dr. Sigismund S. Goldwater, then commissioner of hospitals, for the study of chronic disease. The first research unit was set up with the Columbia University College of Physicians and Surgeons and later with New York University College of Medicine. Originally housed in a reconstructed building on Welfare Island, the research activities have been associated with the Goldwater Memorial Hospital since 1941. City funds for the research council have been supplemented by grants from the late Lucius N. Littauer, Marshall Field, the Rockefeller Foundation, Metropolitan Life Insurance Company and others. Among other speakers at the meeting was Comdr. J. Murray Steele (MC), U. S. Naval Reserve, who discussed principles that had been evolved through a research program by the third medical division (New York University) at Goldwater Memorial Hospital, involving the management of a hospital that will permit the study of "patients to become a part and parcel of their care." The principles involve such points as "the selecting of special types of patients for purposes of study, arrangements to meet the necessities involved in long term observations and tests of a variety of patients during the gradual evolution of chronic diseases, collection of data in the social history other than that immediately necessary to determine eligibility for admission or retention, variability and control of diet, importance of postmortem examination, and close liaison with the patient's hospital origin."

NORTH CAROLINA

Commission Named to Study Medical Care.—Mr. Clarence Poe, Raleigh, on February 28 was named chairman of the recently appointed hospital and medical care commission named by the governor to undertake a study of the needs in North Carolina. Mr. Poe was also named chairman of the executive committee, other members of which include James A. Gray, Winston-Salem, vice chairman; Dr. Carl V. Reynolds, Raleigh, secretary; Dr. James W. Vernon, Morganton, Mrs. Julius Cone, Greensboro, Dr. Paul F. Whitaker, Kinston, Thomas Pearsall, Rocky Mount, Charles A. Fink, Spencer, Charles A. Cannon, Concord, C. C. Spaulding and Dr. William M. Coppridge, Durham. At the first meeting of the commission, February 21, Governor Broughton said it was agreed that the program to be studied by the commission should be comprehensive, based on the statement as originally submitted that "the ultimate purpose of this program should be that no person in North Carolina shall lack adequate hospital care or medical treatment by reason of poverty or low income." It was voted to appoint a committee to study similar undertakings in other states, to get a complete record of hospital needs in various areas and counties of the state, to have special studies made of the needs for hospitalization on the part of the Negroes of the state and to get the benefit of information from the county welfare agencies about inadequacy of hospital and medical care in such counties. Newspapers reported that the program, to be supported by state funds and whatever federal funds are available for this purpose, was proposed by the governor in January before the board of trustees of the University of North Carolina and given unanimous endorsement. Governor Broughton recommends that the present two year medical school at the University of North Carolina School of Medicine be enlarged and increased to provide for a full four year medical course, that an adequate hospital be erected at the medical school with a capacity of not less than 600 and preferably 1,000 beds, that the hospital shall be open to patients from all sections of the state with provision for free medical and hospital service to all patients unable to pay for the service and that other hospitals to serve as local medical centers be established in strategic regions of the state.

TENNESSEE

Vanderbilt Confers First Public Health Degrees.—The degree of master of public health was conferred on Dr. Fridgeir Olason and Dr. Fritz Plotke at the graduation exercises recently of Vanderbilt University School of Medicine, Nashville, marking the first time in the history of the university that such a degree has been granted. Dr. Olason came to Vanderbilt in 1942 from Reykjavik, Iceland, and in the same year Dr. Plotke came from the state hospital in Manteno, Ill. The latter received his degree in medicine from the University

of Leipzig in 1934 but came to this country before the outbreak of the war. He is public health physician at the Chicago State Hospital. Dr. Olason received his medical degree at the University of Iceland in 1938. He then served as a public health physician in a rural district in Iceland and is now studying at Harvard in preparation for his degree as doctor of public health. Dr. Olason is a Commonwealth Fund Fellow.

WASHINGTON

Dr. Schwabland Resigns as King County Health Officer.—Dr. Wallace W. Schwabland, Seattle, has resigned as health officer of King County, effective March 1, a position he held for ten years. He will devote his full time to private practice. Newspapers report that Dr. Emil E. Palmquist, Port Angeles, director of health for Clallam and Jefferson counties, will be named to succeed Dr. Schwabland.

WISCONSIN

Information Please.—The Medical Society of Milwaukee County held a program March 10 entitled "Information Please." The theme was "Endocrine and Metabolic Diseases" and the speakers were Drs. Edward H. Ryneerson, Rochester, Minn., Ralph A. Reis, Chicago, and Norbert Enzer and Timothy J. Howard, Milwaukee.

GENERAL

Medical Book Included in Annual Exhibit.—For the first time since its inauguration twenty-two years ago, the annual exhibit of the Fifty Books of the Year includes a medical book, "Biomicroscopy of the Eye," by Dr. Milton L. Berliner, New York. The volume was selected as one of the year's outstanding examples of book making. Designed by Daniel F. Bradley, it was published by Paul B. Hoeber, Inc., New York. In a review of the exhibit in *Publishers' Weekly*, Lewis F. White said: "Biomicroscopy of the Eye" is the bulkiest and heaviest of the Fifty. It is primarily interesting in consequence of the excellent quality of its 500 illustrations, 40 of which are executed in colored colotype of real brilliance of color." The exhibit opened March 1 at the New York Public Library, under the auspices of the American Institute of Graphic Arts.

Special Society Election.—Mrs. Eleanor Brown Merrill, New York, executive director of the National Society for the Prevention of Blindness, has been chosen president of the National Health Council to succeed Dr. George S. Stevenson, New York, medical director of the National Committee for Mental Hygiene. Other officers include Dr. Walter Clarke, New York, executive director of the American Social Hygiene Association, vice president, to succeed Dr. Kendall Emerson, New York, managing director of the National Tuberculosis Association; Maurice A. Bigelow, Sc.D., New York, president of the American Eugenics Society, secretary, and Dr. William F. Snow, chairman, executive committee, American Social Hygiene Association, treasurer. Mrs. Merrill is the first woman to be elected president of the council since its establishment in 1921. The group is a clearing house of twenty voluntary health organizations with headquarters at 1790 Broadway, New York 19.

Another Racket.—A physician writes from Clayton, N. M., that a man giving the name of William E. Burton Jr., Springfield, Mo., reputedly selling magazine subscriptions, called for treatment for an injury to his lower dorsal spine, which, he claimed, was recent. Burton claimed to have been in the St. Louis Children's Hospital seven years previously for lower extremity atrophies following poliomyelitis. The physician reporting this case states that his examination proved that the man had had poliomyelitis and now has a partially useful right leg and a dorsolumbar scoliosis. X-ray films, however, did not indicate any injury for which he was then claiming treatment. Checks were written against the National Circulation Company, Rockefeller Center, New York, in payment of services, but the company writes that William E. Burton Jr. has no connection with the company. The physician reporting this matter states he does not understand the man's racket; he does not seek change and the persons treating him seem to be out only material and service, since the checks were returned "without payment."

Society News.—The American Association of Plastic Surgeons will hold its annual session in Philadelphia, May 5-7. Dr. Frederick A. Figi, 102 Second Avenue S.W., Rochester, Minn., is secretary-treasurer.—The American Nurses' Association, the National League of Nursing Education and the National Organization for Public Health Nursing will meet in Buffalo, June 5-8. The groups will meet respectively at the Hotel Statler, the Hotel Lafayette and Hotel Buffalo. Mrs. Tessa Klein, 181 Franklin Street, Buffalo, is chairman of the committee on general arrangements.—The American

Psychoanalytic Association will hold a special scientific and executive session in Philadelphia, May 14-15. Council meetings are scheduled for May 13. The association will meet in conjunction with the American Psychiatric Association, which this year is celebrating its centennial.—The American Association of Medical Social Workers will hold its annual meeting in Cleveland, May 22, in the Hotel Cleveland.—The American College of Allergists will hold its first annual meeting at the Palmer House, Chicago, June 10-11.

CANADA

Plaque in Memory of Dr. Jabez Elliott.—A portrait plaque of the late Dr. Jabez H. Elliott, professor of the history of medicine, University of Toronto Faculty of Medicine, was unveiled in the Academy of Medicine of Toronto recently. It is the work of Lieut. Cleeve Horne, O.S.A. Dr. Elliott had served in many activities of the academy of medicine but the *Bulletin* of the Academy of Medicine of Toronto paid special tribute to his work as a member of the library committee, which he began in 1912. He died Dec. 18, 1942.

LATIN AMERICA

Health Activities in Latin America.—The governments of Colombia and the Dominican Republic have effected an agreement with the Institute of Inter-American Affairs to continue and extend cooperative health and sanitation programs. Colombia will contribute \$600,000 over a period of two years beginning July 1, and the Dominican Republic will contribute \$150,000 for its program to be expended over a three year period beginning Jan. 1, 1945.

Typhoid Epidemic.—In La Paz, Bolivia, the first case of typhoid in Sopocachi, a section of La Paz, was reported Dec. 11, 1943. On January 23 a total of 137 cases had been reported, of which 80 were hospitalized and the remainder treated in their homes or in private clinics. Twenty-one patients died. The cause of the epidemic had not been determined up to March 1, but it is believed that it was due to use of contaminated water for irrigation purposes. According to the Health and Sanitation Division *Newsletter*, a large of the city of La Paz has no sewerage facilities.

New Construction.—A laboratory is being organized in Cochabamba, Bolivia, near the medical school of the University of Cochabamba, on land donated to the Inter-American Cooperative Health Service by the city of Cochabamba within the property of the Viedma Hospital. The laboratory will be a one story brick structure with facilities for clinical laboratory and diagnoses and for some research in diseases prevalent throughout Bolivia. In Colombia a new building will be erected in University City for the National School of Nursing. In Mitu, Colombia, a hospital is being constructed to consist of two wooden buildings, one to accommodate patients and the other to contain living quarters for the physician, a consulting room and a treatment room. In Ecuador construction was recently started on the Guayaquil Maternity Hospital. The project consists of six buildings. The center of the group is a T shaped two story administrative pavilion, which is flanked by two L shaped two story pavilions for general ward and private patients. There are three one story pavilions for auxiliary services, such as kitchens, laundry, morgue and living quarters for servants and nuns. The buildings will have a total floor area of 40,000 square feet. The hospital will have a capacity of 200 beds. Plans provide for a future extension to the hospital of 100 beds.

Typhus Control.—Fourteen localities in the vicinity of Quezaltenango, Guatemala, were recently visited by one of the mobile units organized under a typhus control project. Thirty-six new cases of typhus were discovered and 9,461 persons were disinfected.

Care for Workers on Military Highway.—The project to provide medical care for workers on the emergency military highway in Guatemala was terminated during October with the closing of the road construction program. In the future, medical care will be provided to workers on the highway through the antimalarial section of the National Public Health Department and through local departmental health officers.

Medical Care for Rubber Workers.—During October 1943 the Institute of Inter-American Affairs and the Rubber Development Corporation entered into an agreement to insure that medical care will continue to be provided for rubber workers in the departments of Peten, Alta Verapaz, El Quiche and Huehuetenango, Guatemala. Most of the rubber to be gathered is in malaria infested areas. For the year Oct. 1, 1943 to Oct. 1, 1944 the Rubber Development Corporation and its agents will provide at cost for the practical doctors employed on the project all essential needs, including food, shelter and lodging, and will also provide free transportation and com-

munication for them while on duty in the rubber areas. In addition to financing the project, the Institute of Inter-American Affairs will provide technical and general supervision of the program.

Personal.—Dr. George C. Dunham, executive vice president of the Institute of Inter-American Affairs and assistant coordinator in charge of the basic economy department, was recently awarded the Southern Cross by the Brazilian government.—Dr. Walter C. Earle, who is serving as consultant to the division of health and sanitation, arrived in Bogota January 27 to assist in the reorganization of the Colombian Department of Health.

Record Rice Crop.—Record production of rice in the Western Hemisphere has provided welcome wartime additions to food supplies and has replaced in a large part former rice imports from the Far East, it is reported, the greatest expansion in rice acreage taking place in Latin America, which before the war bought large quantities of rice from Asia. According to the U. S. Department of Agriculture, rice production in the Western Hemisphere in the past fifteen years has almost doubled, reaching a figure of more than 200 million bushels in 1943, more than one half of which was produced in South America, one third in North America and the remainder in Central America.

Malaria Control Program.—An extensive malaria control program has been in operation in Haiti in cooperation with the Office of the Coordinator of Inter-American Affairs. Malaria swamps have been drained around six coastal communities having a combined population of 200,000. About 20,000 people have been treated for yaws, tropical skin and blood disease, with 15,000 to 20,000 additional treatments being given weekly. In a release, Ralph S. Howard Jr., chief of the U. S. health mission to Haiti, stated on his arrival in Washington that malaria had been reduced to a secondary health problem in Port-au-Prince. This was accomplished, he said, through installation of 15 miles of ditches and canals to eliminate mosquito breeding swamps, including considerable work around the airport. The rest of the malaria control work involved installation of 15 miles of drainage ditches and canals in and around the towns of Petit Goave, Aux Cayes, Cap Haitien, Port de Paix and Mole St. Nicolas. These projects as well as four yaws clinics established are largely in communities from which workers are drawn for rubber and fiber plantations. Mr. Howard reported that Haiti had seventeen specialists making public health studies under the training phases of the inter-American program. Seven of the men are studying at Harvard University, Boston, and ten at the School of Tropical Medicine at San Juan, P. R.

Government Services.

Communities in Need of Physicians

The United States Public Health Service has recently announced that the following two communities have qualified for federal assistance in obtaining the services of physicians under the recently enacted law authorizing an appropriation of \$200,000 for the relocation of physicians by depositing their required share of the expense money:

Star (Montgomery County), North Carolina.
Hamilton (Harris County), Georgia.

Physicians interested in locating in these communities should communicate with the Surgeon General, United States Public Health Service, Washington (Bethesda Station), D. C.

Industrial Hygiene Division Reorganized

Under the new plan of administration (*THE JOURNAL*, Dec. 11, 1943, p. 983) the present structure of the industrial hygiene division of the U. S. Public Health Service, with the exception of the research section, becomes a division of the bureau of state services. The research section remains in the National Institute of Health and will be known as the Industrial Research Laboratory. The reorganization of the public health service effected by action of the 78th Congress became operative on December 30. Medical Director James G. Townsend is in charge of the division. Personnel in charge of the sections and units comprising the reorganized industrial hygiene division include:

Medical Director Louis Schwartz, dermatoses section.
Senior Sanitary Engineer J. J. Bloomfield, field operations section.
Surgeon Waldemar C. J. Dressen, medical unit.
Sanitary Engineer (R) Harry E. Seifert, engineering unit.
Principal Statistician William M. Gafafer, statistical unit.
Senior Chemist Frederick H. Goldman, chemical unit.

Feb. 19, 1944.

A National Health Service

The white paper on a national health service has at last been issued by the government. It runs to 55,000 words and deals with all the details of a complex problem. The object is to establish a comprehensive health service for all—to ensure that every man, woman and child can get all the advice, treatment and care that may be needed in matters of personal health, that what they get shall be the best medical and other facilities available and that their availability shall not depend on whether or not the people can pay for them or on any other factor irrelevant to the real need.

The government's main reason for recommending changes in medical care is explained by the belief that at this stage of social development the care of personal health should be made available to everybody as a public sponsored service. In spite of the fact that many good services have been built up under public authority by voluntary and private effort, the white paper claims, it is not true that every one can get all the kinds of medical and hospital service he may require. This still depends too largely on where people happen to live, their age or vocation or what happens to be the matter with them. Nor is the care of health wholly divorced from ability to pay, though great progress has been made in this direction. Hospital and specialist services have grown up without a national or even an area plan. One area is well served, another sparsely. One hospital may have a long waiting list, while another not far away could admit patients at once. The time has come, it is concluded, when hospital service must be planned as a whole.

THE SCOPE OF A COMPREHENSIVE SERVICE

The proposed service, it is held, must be comprehensive in two senses—available to all and covering all necessary forms of health care. The whole field of medical advice—at home, in the consulting room, in the hospital or sanatorium or wherever else is appropriate, from personal or family doctor to specialists and consultants of all kinds, from the care of minor ailments to major diseases—must all be covered. It must include ancillary services such as nursing. Every one must be sure of a general medical adviser whom he can consult and, when the need arises, of access to specialists in medicine and surgery. All this cannot be perfected at a stroke of the pen on an appointed day, it is acknowledged, but the framing of such a service must be the aim.

ORGANIZATION OF THE SERVICE

Central responsibility, the government says, must rest in the minister of health, who is answerable directly to Parliament. At his side but independent of him will be created a special professional and expert body—the Central Health Services Council. The council will express the expert view on any general technical aspect of the service. As there cannot be dual responsibility, its work will be consultative and advisory, not executive. The council will be primarily medical in its makeup, because the main technical aspects of the health service will be medical. But it will not be wholly medical, as it will need to express an expert view on many questions—hospital administration, nursing, pharmacy and auxiliary services which involve other experts. The members will be appointed by the minister in consultation with the professional and other organizations concerned.

Local organization must inevitably be more complex, it is pointed out. The new service has to include hospitals and

institutional services for the sick in general, mental cases, infectious diseases, tuberculosis, maternity care and every other general and special need. It has to include the many kinds of service provided in local clinics, a family doctor service and many ancillary services such as nursing, health visiting and midwifery. It must range from the one extreme of highly specialized services requiring relatively few centers for the country as a whole to the other extreme involving a large number of local clinics and arrangements for care in the individual home. Suggestions have been made too for a completely new kind of local authority—sometimes proposed as a vocational or technical body like the special kind of central advisory organization mentioned. Both the principles applied to the central organization—democratic responsibility and professional guidance—apply to local as well as national organization.

GENERAL PRACTITIONER SERVICE

The arrangements for general medical practice are stated to be the most important part of the proposals for a national health service. The family doctor is the first line of defense in the fight against ill health, and it is through him that access will be had to other forms of treatment. Every one must be free to choose the doctor whom he consults from among those available. The fact that a public organization ensures the doctor's services must not destroy the sense of choice and the personal association which is at the heart of family medical care. The doctor must remain free to direct his clinical knowledge and personal skill as seems to him best. A system by which he becomes simply an employee of the local authority has been suggested, but opinion is sharply divided as to this. Many experienced and highly skilled doctors would refuse to be so employed, because they would lose their freedom. Others would welcome the system. The government has decided that the change to such a system would be too abrupt and is unnecessary. An extension of the present panel system has been suggested, but the government finds two reasons against this. First, it gives no effective means of ensuring a proper distribution of doctors. Second, developments in the modern technic of medical practice point to the need for change in any future system. A recent report of the Medical Planning Commission of the British Medical Association states "The days when a doctor armed with his stethoscope and his drugs could offer a fairly complete medical service are gone. For efficient work he must have at his disposal modern facilities for diagnosis and treatment, and often these cannot be provided by a private individual." The organization of general practice on a group or cooperative basis is then suggested. The government fully agrees and places group practice in the forefront of the plans. Hence the intention is to establish "health centers" specially designed and equipped for collaboration of the group. The centers will comprise individual consulting rooms, reception and waiting rooms and rooms for simple laboratory work, nursing and secretarial staff and facilities for minor surgery.

PRIVATE PRACTICE

It is hoped that the great majority of doctors will take part in the new service, and therefore it is not proposed to prohibit doctors who enter the service from treating in their private practices any patients who do not desire to take advantage of the new public arrangements. But it will be necessary to see that the interests of patients in the public service do not suffer thereby. This will be done by reducing as may be required the number of persons a doctor is permitted to have "on his list" under the new scheme and so reducing his remuneration from public funds. There is held to be a strong case for requiring young doctors when they leave hospitals and enter the public service to go through a short period as assistants to more

experienced practitioners. The government proposes to do this and also to require the young doctor during his early years to give all his time to the public service when this is needed.

HOSPITALS

A fully organized system of hospitals will be the keynote of the national health service. The new hospital service must be complete and ready of access. It must include general and special hospitals, infectious disease hospitals, sanatoriums for tuberculosis, accommodations for maternity care and the chronically sick, and for rehabilitation. Ancillary hospital services such as pathologic and x-ray examination, electrotherapy and ambulance must also be provided. The voluntary hospital is the oldest type of institution established here and is the basis of the medical schools. The government desires the fullest cooperation between voluntary hospitals and the steadily developing system of hospitals provided by the local authorities, which will be part of the health service.

CONSULTANTS

The greatest gap in the health services provided by the present national health insurance scheme is the lack of a consultant service. This will be provided under the new program. It can best be based on the hospital services. The main consultant facilities now are inevitably concentrated at the medical teaching centers. The consultant service still needs to be organized with the teaching center as its focus, but it must be spread over a wider area by encouraging consultants taking part in to live and work further afield. Their function will normally be of regular and frequent visits for consultation to both major hospitals and the outlying general practitioner hospitals and also to the health centers and clinics and, in case of need, to the patient's home at the request of the general practitioner. Remuneration can be on either a full time or a part time salary basis.

THE REACTION OF THE MEDICAL PROFESSION

As the white paper has only just been published, the medical journals have not yet been able to comment, but the British Medical Association immediately issued to the press an official statement which described the physicians' reaction as a "cautious welcome." The association states that the medical profession is in the fullest sympathy with the government's objective to make available to everybody who needs it, irrespective of age, sex or occupation, an equal opportunity to take advantage of a comprehensive health service. The profession accepts the principles laid down by the government of freedom to use or not to use the service and freedom for doctors to work inside the service, outside the service, or both. The profession welcomes the general policy of building on existing foundations, of welding together what is already there, adapting and adding to it, until a comprehensive service is achieved, however long that may take. But many points remain to be clarified, such as the experimental character of the health centers, the relation of individual family doctors to hospitals, the mode of appointing and distributing consultants, the compensation for loss of capital value of general practices, the machinery by which the public will intimate its desire to avail itself of the service in whole or in part, the future of voluntary hospitals and contributory schemes and the functions of the proposed Central Medical Board. The profession sympathizes too with the government's desire to secure an equitable distribution of doctors. But, in the public interest, individual doctors must be protected from unwarranted or unnecessary interference with the type or place of their practice. No attempt must be made, it is held, to regiment the profession by imposing on new entrants conditions which encourage the development of a whole time, state salaried

service. No rigid form of health center organization should be established until widespread experiment has been undertaken. In sum, the white paper is thought to provide a framework within which it is possible to evolve a good, comprehensive medical service, though its worth to the public and acceptability to the profession will depend on the clarification and negotiation of many important points.

Although the new service builds on the past, it profoundly alters the whole structure of medical practice. At first the profession was confronted with the danger of a whole time service, so that doctors would become simply government servants and medical practice would be a branch of the civil service. But the firm resistance of the representatives of the profession, in conferences with the government, averted this danger and also maintained the right to practice outside the service. Though in favor of reform, the profession—excepting a minority of socialists—was averse to such drastic change as was proposed. But the government has considered the views of the profession in everything and given way on the two fundamental points mentioned. The proposals have to be discussed by Parliament and no doubt will be further modified. In the solution of difficulties the characteristically English method of compromise, already in evidence in the white paper, will come into play.

Martyrs to the X-Rays

The unveiling of a tablet at the London Hospital to the memory of four pioneers in the use of x-rays recalls the danger encountered before the need for precautions was understood. The tablet was unveiled by Dr. J. H. Sequeira, the dermatologist under whom they worked. Ernest Harnack began taking photographs in 1896 with a primitive apparatus. He was the first member of the hospital staff to suffer from x-ray dermatitis and had to relinquish his work in 1909. In spite of grave mutilation, he lived until 1943, dying at the age of 72. Ernest Wilson joined the staff in 1899 and after only a year contracted dermatitis of the fingers. He continued to work until 1904 but died of rapid cancer in the following year at the age of 39. Reginald Blackall joined the staff when only 18 and was successful in the treatment of ringworm in children. With Dr. Sequeira he carried out experiments in the use of x-ray filters. In 1925 he succumbed to cancer at the age of 44. When Harold Suggars joined the hospital in 1903 some of the risks of exposure to x-rays were known, and he was the first worker to wear lead-lined gloves and body protection. But he developed cancers on the trunk, face and eyelid and finally became almost totally blind from double cataract. He died in 1943, showing amazingly cheerful patience and courage. The tablet is in the x-ray department and reads "These four friends, as pioneer radiographers, devoted their lives to healing. Their work in the development of the x-rays cost them their health. This they gladly gave in the service of the London Hospital."

Marriages

EDWARD F. FLEMING, St. Paul, Neb., to Miss Elizabeth Delores Kelly of Omaha, February 21.

AUGUSTA HOLMSTOCK, Philadelphia, to Mr. Jacob J. Kressler of Worcester, Mass., December 31.

SAM GAINES STUBBINS JR., Birmingham, Ala., to Miss Billie Jane Malm of Cleveland, February 29.

BRUCE JOHN BREWER, Milwaukee, to Miss Kathryn Tilley in Fairfield, Ohio, February 12.

ROSCOE L. FISHER to Miss Frances L. Kelly, both of York, Pa., February 19.

HAROLD S. RAFAL to Miss Sheila H. Kirmayer, both of New York, March 4.

Deaths

George L. Le Fevre ☉ Muskegon, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1891; in 1933 president of the Michigan State Medical Society and for many years councilor of the eleventh district; president of the Muskegon County Medical Society in 1905 and again in 1922; medicolegal adviser of the society for many years; formerly a member, and president of the Michigan State Board of Registration in Medicine for sixteen years; fellow of the American College of Surgeons; identified with the Mercy Hospital as president, chief of staff, chairman of the advisory committee and chief emeritus; in 1936 a life sized oil portrait of him was presented to the hospital in appreciation of his many years' service; on the staff of the Hackley Hospital; for many years president of the board of trustees of the Muskegon County Sanatorium; in 1920, as a member of the city commission, served on the county board of supervisors; at one time city and county physician; a member of the board of directors of the Union National Bank since 1911 and president from 1923 until the bank was merged with the Hackley National Bank to form the Hackley Union National Bank, where he had been chairman of the board since 1928; in 1942 made a Knight of St. Gregory by Pope Pius XII; served as vice chairman of the board of trustees for Muskegon County Museum and as president of the Muskegon Industrial Foundation; member of the Rotary Club; died March 3, aged 78, of influenzal pneumonitis.

William Gray Turnbull ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1906; assistant professor of medicine at his alma mater; became medical director of the Pennsylvania State Sanatorium for Tuberculosis number 2, Cresson, Pa., when it was established in 1912 and remained there for many years; formerly deputy state secretary of health with supervision over several state sanatoriums; served as a member of the advisory board of the state department of health; presented with the Strittmatter Award by the Philadelphia County Medical Society in 1937; during World War I was in charge of the General Hospital at Waynesville, N. C., with rank of lieutenant colonel; lieutenant, medical reserve corps, U. S. Army, not on active duty; since 1928 superintendent of the Philadelphia General Hospital where he died while walking through the grounds, March 11, aged 67, of heart block.

Radie Garfield Snyder ☉ New York; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1904; member of the American Rheumatism Society and the New York Academy of Medicine; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; at one time assistant clinical professor of medicine at the Columbia University College of Physicians and Surgeons; professor of medicine at the New York Polyclinic Medical School and Hospital, 1922-1923; for many years chief of the arthritis clinic at the Hospital for Ruptured and Crippled, now known as the Hospital for Special Surgery; served on the staffs of the New Rochelle Hospital, New Rochelle, Jamaica Hospital, Jamaica, and St. Agnes Hospital, White Plains, N. Y.; died February 25, aged 63, of gastric ulcer.

William Mann Randolph, Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1890; member of the Medical Society of Virginia; captain of Troop K, Albemarle Light Horse, from 1892 to 1897, and a major in the 17th Infantry, Virginia Volunteers, 1898 to 1904; served as a major in the medical corps of the U. S. Army during World War I; at one time adjunct professor of surgery and instructor in genitourinary surgery at his alma mater; formerly on the staffs of the Calumet and Arizona Hospital Department and the Copper Queen Hospital, Bisbee, Ariz.; served as a member of the school board of Tombstone, Ariz.; clinician with the outpatient department, tuberculosis control, Virginia Department of Health, Richmond; died January 25, aged 74, of heart disease.

Edward Everett Webber, Duluth, Minn.; Jefferson Medical College of Philadelphia, 1902; member of the Minnesota State Medical Association; fellow of the American College of Surgeons; served as president of the West Duluth Business Men's Club and as a member of the chamber of commerce; chief surgeon for the Duluth, Missabe and Iron Range Railway; served as mayor of Chisholm and as health officer of Mountain Iron and Kinney; formerly president of the school board of Buhl; member, attending staff, St. Luke's and St. Mary's hospitals; surgeon in charge and owner of the Webber Hospital, where he died January 17, aged 65, of influenzal bronchopneumonia and chronic cirrhosis of the liver.

Charles Frederick Baker ☉ Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1902; member of the Radiological Society of North America, Inc., and the American College of Radiology; specialist certified by the American Board of Radiology, Inc.; on the staffs of the East Orange General Hospital, East Orange, Essex Mountain Sanatorium, Verona, Irvington General Hospital, Irvington, Orange Memorial Hospital, Orange, Fitkin Memorial Hospital, Neptune, Babies Hospital-Coit Memorial, Newark Eye and Ear Infirmary, Presbyterian Hospital and the Hospital of St. Barnabas and for Women and Children, where he died March 6, aged 67.

Fred Maurice Spalding, Boston; Harvard Medical School, Boston, 1897; member of the Massachusetts Medical Society and the American Ophthalmological Society; member and past president of the New England Ophthalmological Society; instructor in ophthalmology at his alma mater from 1902 to 1920; recently returned to work in the clinic and for many years ophthalmic surgeon, chief of the ophthalmic service and consulting ophthalmic surgeon, Massachusetts Eye and Ear Infirmary; for many years visiting ophthalmologist at the New England Deaconess Hospital and the New England Baptist Hospital, where he died January 24, aged 73, of pneumonia.

William H. Williams ☉ Lebanon, Ind.; Medical College of Indiana, Indianapolis, 1897; formerly councilor of the Ninth District of the Indiana State Medical Association and secretary of the Boone County Medical Society; fellow of the American College of Surgeons; president of the Business and Professional Men's Realty Company and vice president and director of the Union Federal Savings and Loan Association; at one time medical director and owner of the Williams Hospital, now known as the Witham Memorial Hospital, where he was a member of the staff and where he died January 13, aged 75, of intestinal obstruction and paralytic ileus.

Henry Richmond Slack, La Grange, Ga.; Atlanta Medical College, 1891; member of the Medical Association of Georgia; also a pharmacist; past president of the La Grange Medical Society; co-founder and for many years president of the Georgia Pasteur Institute, Atlanta; at one time physician in charge of the La Grange Sanatorium; co-founder of the public school system; from 1886 to 1898 secretary of the Georgia State Board of Pharmacy; life member of the Georgia Pharmaceutical Association; died in the Emory University Hospital, Emory University, January 16, aged 81, of pneumonia and uremia secondary to sulfonamides.

Richard Dunckley Sessions ☉ Natchez, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1892; member of the Southeastern Surgical Association; fellow of the American College of Surgeons; served as vice president of the Mississippi State Medical Association, president of the Adams County Medical Society and the Homochitto Valley Medical Society; visiting surgeon, Natchez Sanatorium; surgeon, Natchez and Southern, Yazoo and Mississippi Valley and Mississippi Central railways and the Missouri Pacific Railroad Company; died January 24, aged 74.

Roy Wilton Dunlap ☉ Tulsa, Okla.; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1901; past president of the Anderson (Texas) County Medical Society and the Tulsa County Medical Society; served in the medical corps of the U. S. Army during World I; instructor in anatomy at his alma mater from 1902 to 1904; at one time on the staff of the International and Great Northern Railroad Employees' Hospital, Palestine, Texas; past president of the Rotary Club of Palestine; examining physician at the city induction center; died January 29, aged 65.

Isaac Preston Seiler ☉ Piketon, Ohio; Ohio Medical University, Columbus, 1900; served as mayor of Piketon; for many years councilor of the Ninth District of the Ohio State Medical Association; formerly secretary of the Pike County Medical Society; executive secretary of the Pike County Republican Committee; for many years president of the school board of Piketon; served as a lieutenant in the medical corps of the U. S. Army during World War I; died in the Mercy Hospital, Portsmouth, January 25, aged 66, of aneurysm of the heart.

Linda Gage Roth, Battle Creek, Mich.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1904; formerly dean of the Kellogg School of Physical Education and later dean of women and school physician, Battle Creek College; a charter member and past president of the Altrusa Club; served as president of the Michigan Student Health Association and as a member of the American Association of University Women; formerly on the staff of the Battle Creek Sanatorium; died January 11, aged 70, of myelogenous leukemia.

Halbert Hammond Acker, Anderson, S. C.; Medical College of the State of South Carolina, Charleston, 1912; member of the city board of health; on the staff of the Anderson County Hospital; died January 20, aged 56, of heart disease.

Arthur Robert Adams Ⓢ Macomb, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; on the staff of the Phelps Hospital; died in St. Francis Hospital, Peoria, January 21, aged 74, of uremia.

Jasper M. Adams, Canton, Ill.; American Medical College, St. Louis, 1889; member of the Illinois State Medical Society; died in the Graham Hospital, Canton, January 24, aged 84, of chronic valvular heart disease and cardiac decompensation.

Yves Ardoin, Ville Platte, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1908; fellow of the Royal Institute of Public Health and Hygiene of London, England; charter member of the local Rotary Club, of which he was past president; owner of the Ardoin Sanitarium and Clinic; died January 20, aged 63.

Charles Henry Artz, Marion, Ohio; Michigan College of Medicine and Surgery, Detroit, 1893; died November 27, aged 77, of valvular insufficiency.

William James Astrapp, South Pittsburg, Tenn.; Meharry Medical College, Nashville, 1908; died suddenly January 10, aged 60.

Novatus Lee Barker, West Point, Ga.; Emory University School of Medicine, Atlanta, 1917; member of the Medical Association of Georgia; formerly on the staffs of the Wesley Memorial, Grady and Piedmont hospitals, Atlanta, and Coleman Sanatorium, Eastman; died in Fountain City, Tenn., January 19, aged 79, of heart disease.

Carlton M. Beebe, Sparta, Wis.; Rush Medical College, Chicago, 1889; College of Physicians and Surgeons, New York, 1891; served during World War I; captain, medical reserve corps, U. S. Army, not on active duty; formerly a member of the Sparta Clinic; on the staffs of the Monroe County Insane Asylum and St. Mary's Hospital; attending physician, state public school; a director of the Farmers National Bank and president of the city water commission; died January 21, aged 77, of uremia.

Kurt Friedrich Behne Ⓢ Los Angeles; Vereinigten Friedrichs-Universität Medizinische Fakultät, Halle-Wittenberg, Prussia, Germany, 1908; member of the Radiological Society of North America, Inc.; formerly assistant professor, University Woman's Hospital, Erlangen, Bavaria; died January 15, aged 58.

William Herron Cameron, Daytona Beach, Fla.; Western Pennsylvania Medical College, Pittsburgh, 1899; fellow of the American College of Physicians; one of the charter members of the American Radium Society; recording secretary of the Allegheny County (Pa.) Medical Society in 1911 and 1912 and assistant secretary and manager of sessions and exhibits of the Medical Society of the State of Pennsylvania from 1914 to 1919; died January 27, aged 69.

Thomas Lynch Coll, Cambridge, Md.; Baltimore Medical College, 1909; member of the Medical and Chirurgical Faculty of Maryland; physician for the county draft board; for many years county coroner; served as county and federal jail physician; member of the Lions Club; on the staff of the Cambridge-Maryland Hospital; died January 4, aged 58.

Montgomery Adams Crockett, Cambridge, Mass.; Bellevue Hospital Medical College, New York, 1886; formerly adjunct professor of surgery and clinical gynecology at the University of Buffalo Medical Department; served on the staffs of the Buffalo General and Riverside hospitals, Buffalo; died January 7, aged 83, of arteriosclerotic heart disease.

Gordon Ambrose Dockery Ⓢ Franksville, Wis.; Rush Medical College, Chicago, 1936; killed when the automobile in which he was driving was struck by a train, January 6, aged 32.

David Beale Ealy, Moundsville, W. Va.; Maryland Medical College, Baltimore, 1912; member of the West Virginia State Medical Association; president of the Marshall County Medical Society; for ten years coroner of Marshall County; served during World War I; elected a member of the West Virginia Senate from the second district in 1938 and served during the regular sessions in 1939 and 1941; died February 24, aged 55, of heart disease.

Donald Maurice Gildersleeve, New York; Long Island College Hospital, Brooklyn, 1912; served overseas during World War I; formerly demonstrator of anatomy at his alma mater; at one time attending surgeon on the staff of the Hospital of St. Giles the Cripple, Brooklyn; died in the Veterans Administration Facility January 18, aged 54.

Edwin Johnson Gillette, Londonderry, N. H.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; member of the New Hampshire Medical Society; died in West Windham recently, aged 79, following an operation for hypertrophy of the prostate.

Horace L. Goodman Ⓢ Ronceverte, W. Va.; Medical College of Virginia, Richmond, 1901; past president of the Greenbrier Valley Medical Society; served as vice president of the West Virginia State Medical Association and since 1941 as councilor of the Sixth District; fellow of the American College of Surgeons; served as attending specialist (surgery) U. S. Public Health Service at Alderson; surgeon in charge and superintendent of the Greenbrier Valley Hospital; died February 28, aged 67, of cardiac decompensation.

Charles Graef, New York; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1896; member of the Medical Society of the State of New York; formerly professor of ophthalmology at the Fordham University School of Medicine; consultant ophthalmologist for the medical advisory board during World War I; consultant ophthalmologist at the Lincoln Hospital; consultant ophthalmologist and otologist, Fordham Hospital; died February 27, aged 72, of chronic myocarditis, coronary sclerosis and cerebral thrombosis.

William Peter Grimaud, Medford, Okla.; Barnes Medical College, St. Louis, 1906; died in an Enid hospital January 6, aged 60.

Andrea E. Hall, Virginia, Minn.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1897; assistant city health officer; at one time company doctor for the Virginia and Rainy Lake Lumber Company at Cusson; died January 13, aged 69.

James White Handly, Nashville, Tenn.; University of Tennessee Medical Department, Nashville, 1887; member of the Tennessee State Medical Association; fellow of the American College of Surgeons; formerly professor of genitourinary diseases at his alma mater; at one time medical director of the Independent Life Insurance Company; for many years chief surgeon for the Tennessee Central Railway; died in St. Thomas Hospital January 6, aged 77.

Arthur Ceberry Haney, Russellville, Ark.; University of Oklahoma School of Medicine, Oklahoma City, 1914; member of the Arkansas Medical Society; past president of the Pope County Medical Society; served during World War I; medical director and owner of the Haney Eye, Ear, Nose and Throat Hospital; died suddenly December 22, aged 54.

Charles Daniel Holliger Ⓢ Stockton, Calif.; University of California Medical School, San Francisco, 1916; member of the Radiological Society of North America, Inc.; died in the Dameron Hospital December 13, aged 60.

Clarence Albert Holmes, New York; Columbia University College of Physicians and Surgeons, New York, 1904; member of the Medical Society of the State of New York; served on the staffs of the Fordham Hospital and the Union Hospital, where he died January 27, aged 64.

O. B. Humston, Franklinton, Ky.; Louisville Medical College, 1880; died in December, aged 87.

Isaac S. Hunt, Freedom, Okla. (licensed in Oklahoma under the Act of 1908); member of the Oklahoma State Medical Association; died recently aged 82.

James Edgar Jeffery, Ordway, Colo.; Ensworth Medical College, St. Joseph, Mo., 1899; served as county coroner and health officer of the town of Ordway; for many years local physician for the Missouri Pacific Railroad; died December 21, aged 74.

Theresa Kline Jennings, Streator, Ill.; Dunham Medical College, Chicago, 1901; served as health officer; died January 6, aged 76.

Edward Townsend Jones, Atlantic City, N. J. (licensed in Ohio in 1896, and New York in 1903); died in the New Jersey Memorial Home for Disabled Soldiers, Sailors, Marines and Their Wives and Widows, Vineland, December 30, aged 94, of pneumonia.

Peter Wilson Leitzell, Benton, Wis.; Jefferson Medical College of Philadelphia, 1896; member of the State Medical Society of Wisconsin; county coroner for many years; died January 5, aged 68.

John Edward Lind, Washington, D. C.; George Washington University School of Medicine, Washington, 1909; specialist certified by the American Board of Psychiatry and Neurology, Inc.; clinical professor of psychiatry at his alma mater; on the staff of St. Elizabeths Hospital; was shot and killed February 21, aged 55.

John Philip Lobenhoffer, San Anselmo, Calif.; Tennessee Medical College, Knoxville, 1894; died December 26, aged 74.

Charles L. Moore * Cleveland; Cleveland Homeopathic Medical College, 1899; served in the medical corps of the U. S. Army during World War I; member of the Milk Commission of Cleveland; for many years on the staff of the Grace Hospital; on the staff of the Huron Road Hospital, East Cleveland; instantly killed when the automobile in which he was driving was struck by a train, January 6, aged 70.

John William Philpott, Fort Madison, Iowa; College of Physicians and Surgeons, Keokuk, 1878; University of Vermont College of Medicine, Burlington, 1884; formerly physician in charge of the Iowa State Penitentiary Hospital; died in the Sacred Heart Hospital January 8, aged 87.

Marcus Rice Piersol, Cairo, Neb.; Lincoln Medical College, 1901; died January 13, aged 72, of heart disease.

Oscar R. Quaintance, Slate Mills, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1873; member of the Medical Society of Virginia; served as president of school board; died January 3, aged 93, of pneumonia following influenza.

Clifford Bertram Rowell, Buffalo; Detroit College of Medicine, 1894; University of Buffalo School of Medicine, 1895; died December 31, aged 75.

Onal Arthur Sale * Neosho, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1917; member of the Radiological Society of North America, Inc.; part owner and medical director of the Sale-Bowman Hospital; died in the Freeman Hospital, Joplin, January 27, aged 52, of coronary occlusion.

Joel E. Saunders, Grasscreek, Ind.; Curtis Physio-Medical Institute, Marion, 1895; died in St. Joseph Hospital, Logansport, January 11, aged 71.

Vincenzo Armando Savoia, Brooklyn; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1902; member of the Medical Society of the State of New York; formerly a member of the board of education; served in the nose, ear and throat clinic of the Lutheran Hospital and as attending physician, Unity Hospital; died January 19, aged 67, of coronary thrombosis.

John William Schelpert, St. Petersburg, Fla.; Bellevue Hospital Medical College, New York, 1889; died January 13, aged 85, of coronary occlusion.

Frank L. Secoy * Sioux City, Iowa; State University of Iowa College of Medicine, Iowa City, 1911; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World I; for many years on the staff of St. Vincent's Hospital; on the staff of Methodist Hospital; died January 23, aged 57, of injuries received in a collision between the automobile in which he was driving and a street car.

William Albert Sibbett, Douglas, Ga.; Atlanta School of Medicine, 1910; University of the South Medical Department, Sewanee, Tenn., 1909; honorary member of the Medical Association of Georgia; served in the medical corps of the U. S. Army during World War I; died in the Veterans Administration Facility, Atlanta, December 7, aged 58.

Benjamin W. Slover, Blanchard, Okla.; Barnes Medical College, St. Louis, 1901; member of the Oklahoma State Medical Association; president of the McClain County Medical Society; past president of the Blanchard Lions Club; died in the Wesley Hospital, Oklahoma City, January 8, aged 70, of heart disease.

George Adam Smith, Black Creek, N. C.; Louisville Medical College, Louisville, Ky., 1887; died in Fremont January 7, aged 84, of angina pectoris.

Demetrius Staneff * Chicago; Cincinnati College of Medicine and Surgery, 1892; died in the Wesley Memorial Hospital January 2, aged 81, of chronic myocarditis and pneumonia.

Morris Dan Stepp * Cleveland; Western Reserve University Medical Department, Cleveland, 1893; formerly assistant clinical professor of surgery at his alma mater; specialist certified by the American Board of Surgery; fellow of the

American College of Surgeons; consulting surgeon, St. Luke's Hospital; chief surgeon, Pennsylvania Railroad; consulting surgeon, New York Central Railroad; died in East Cleveland, Ohio, January 14, aged 71, of coronary thrombosis.

Thomas Hill Stewart Jr. * Lieutenant Colonel, U. S. Army, retired, Eastman, Ga.; Atlanta Medical College, 1914; Army Medical School, 1924; entered the medical corps of the U. S. Army as a first lieutenant in 1920; promoted as a captain, a major and in 1937 as a lieutenant colonel; retired August 31, 1941; served during World War I; on the staff of the Coleman Sanatorium; died in Savannah January 6, aged 51, of coronary thrombosis.

John Wallace Stokes * Southold, N. Y.; Jefferson Medical College of Philadelphia, 1904; chairman of the board of Southold Park Commissioners and president of the board of the Southold Library; past president of the Eastern Long Island Hospital Association; on the staff of the Eastern Long Island Hospital, Greenport, where he died January 12, aged 65, of uremia.

Arthur Lile Stone, Camden, N. J.; Boston University School of Medicine, 1898; member of the Medical Society of New Jersey; director of public health for Camden; formerly health officer of Pittsfield, Mass.; served during World War I; past president of the New Jersey Health Officers' Association; died February 17, aged 70, of heart block.

William Henry Sullivan, Cleveland, Tenn.; Chattanooga Medical College, 1899; member of the Tennessee State Medical Association; served as Bradley County physician; on the staff of the Physicians and Surgeons Hospital; died January 15, aged 73, of coronary thrombosis.

J. William Trisler, Glendale, Ohio; Jefferson Medical College of Philadelphia, 1884; died January 18, aged 85, of senility.

Ralph Randolph Trueblood, Lawrenceville, Ill.; Hospital College of Medicine, Louisville, Ky., 1896; member of the Illinois State Medical Society; surgeon for the Baltimore and Ohio and New York Central lines; served during World War I; for many years physician for the Indian Refining Company; secretary and past president of the Lawrence County Medical Society; a charter member of the Rotary Club; died January 6, aged 69.

Joseph William Walsh, Rockville Center, N. Y.; Long Island College Hospital, Brooklyn, 1897; died January 1.

Morton Smith Wardner, Lackawanna, N. Y.; Rush Medical College, Chicago, 1884; died in Chicago in December, aged 93.

Rufus Clyde Webb, Rayne, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1912; died in a hotel at Birmingham, Ala., January 4, aged 55, of coronary thrombosis.

George M. Woodman, Westbrook, Maine; Medical School of Maine, Portland, 1897; member of the Maine Medical Association; served as a member of the board of health of Westbrook; past president of the Cumberland County Medical Society; charter member of the Rotary Club; medical superintendent of the Westbrook Hospital; died January 27, aged 71, of heart disease.

William Byrd Young, Nashville, Tenn.; University of Tennessee Medical Department, Nashville, 1888; a charter member and past president of the White County Medical Society; a charter member of the Upper Cumberland Medical Society; for many years an official of Tennessee Products Corporation; died January 3, aged 78.

KILLED IN ACTION

Anthony John Gramling, Milwaukee; Marquette University School of Medicine, Milwaukee, 1940; formerly resident physician at the Columbia and Milwaukee Children's hospitals; commissioned a first lieutenant on Feb. 2, 1942 and later promoted to captain in the medical corps, Army of the United States; killed in action in Italy, January 10, aged 29.

CAPT. ANTHONY JOHN GRAMLING,
M. C., A. U. S., 1914-1944

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the
Food and Drug Administration of the
Federal Security Agency

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D. D. N. J. and foods, F. N. J. The abstracts that follow are given in the briefest possible form. (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Betene—L. H. Stewart Corporation, Rochester, N. Y. Shipped Nov. 5, 1941. Composition essentially a mixture of dried skim milk, dried egg yolk, soy bean tissues, wheat bran, wheat germ, salt, agar agar, calcium phosphate, chondrus (Irish moss) and saccharin, flavored with cocoa, vanilla and coumarin, together with certain added vitamin substances. Misbranded because label falsely suggested that when consumed as directed, product would increase weight, give vigor and vitality to the user, and constitute a sure, safe and effective way to reduce—[D. D. N. J., F. D. C. 732, April 1943] Also misbranded under the provisions of the law applicable to foods, as reported in F. N. J. 3840.

Cook's Laxative Cold Breakers—Thomas E. Cook Chemical Company, Frederick, Md. Shipped Sept. 16, 1941. Composition in each tablet 1 grain of acetophenetidin, 0.26 grain of eucalyptus sulfate and unreported amounts of camphor, aloin, podophyllin and cayenne pepper. Misbranded because of false and misleading label representations that product was a remedy for colds and accompanying ailments. Further misbranded because of label claim, "They Contain No Quinine," whereas product did contain eucalyptus, a eucalyptus alkaloid which has properties generally similar to those of quinine. Also misbranded because the concern maintained no laboratory in spite of this intimation in its name, but merely repackaged medicines made in other establishments—[D. D. N. J., F. D. C. 735, April 1943].

Dromgooles Bitters—McCullough Drug Company, Lawrenceburg, Ind. Shipped Jan. 2, 1942. Composition extracts of plant drugs, including a laxative and an alkaloid bearing drug, with iron and ammonium citrate, alcohol and water. Misbranded because labeling failed to give directions for use and because of false and misleading label statements. "Bitters. Uterine Tonic, Sedative and Antispasmodic Aid in the relief of Periodic Pain and Distress." [D. D. N. J., F. D. C. 705, April 1943].

Endocrine Extract Formula Nos. 2, 131 and 157—Bleything Laboratories, Los Angeles. Shipped between Oct. 17, 1940, and July 2, 1941. Formula No. 2 adulterated because strength differed from and quality fell below representation of 33 cc., 3 mg. of the crystalline principle of thyroid and 20 mg. of the crystalline principle of entire ovary, whereas it contained no detectable amount of these ingredients. Formula No. 131 adulterated because strength differed from and quality fell below label representations of 33 cc., 3 mg. of the crystalline principle of thyroid and 10 mg. of the crystalline principle of the male orchic gland, since the presence of neither was detectable. Formula No. 157 adulterated because strength and quality fell below label representation of 33 cc., 3 mg. of crystalline principle of thyroid, 10 mg. of crystalline principle of the pineal gland and 5 mg. of the crystalline principle of the male orchic gland, none of which were detectable. All three products misbranded because of false and misleading label declaration regarding these drugs—[D. D. N. J., F. D. C. 717, April 1943].

Estromone—Endo Products, Inc., Richmond Hill, N. Y. Shipped between Dec. 28, 1939, and Nov. 20, 1940. Adulterated because strength and quality fell below label representations that the tablets possessed a biologic activity equal to 2,000 international units of estrogenic hormone, whereas some of them did not—[D. D. N. J., F. D. C. 719, April 1943].

Hill's Swabbed Applicators with Tongue Blade—Wetmore Centaur Corporation, New York. Shipped Nov. 27, 1941. Adulterated because purity fell below its declared standard, since it was designated "sterilized," whereas it was not sterile, but was contaminated with aerobic, anaerobic or facultative anaerobic micro organisms. Misbranded because of false and misleading representations that the product was sterilized, and the claims "The Modern Way of Treating sore throats, cuts, wounds, ear and nose ailments. The Ideal Way of safeguarding your health. For eye ear and nose treatment. Especially useful to mothers treating infants. Specially made for Throat Treatment."—[D. D. N. J., F. D. C. 700, February 1943].

Hi-V Vitamins—Hi-V Vitamin Corporation, New York. Shipped Jan. 19, 1942. Misbranded because label bore false and misleading claims regarding efficacy of the product in restoring and maintaining health and preventing or correcting disease conditions, and represented that it con-

tained all the vitamins essential in normal nutrition, whereas it did not contain riboflavin or nicotinic acid, two substances whose absence from the diet may cause vitamin deficiency diseases. Further misbranded because of false and misleading representations in accompanying circular that the average individual requires vitamin supplements of this type to obtain maximum health, and that he is likely to be suffering from lack of vitality, energy, appetite and proper digestion because of inadequate vitamin intake from his food, that consumption of this product as directed would in most cases prevent or correct the disease conditions resulting from inadequate vitamin intake, and that it contained all the vitamins essential in normal nutrition, whereas it did not—[D. D. N. J., F. D. C. 691, February 1943]. Also misbranded under the provisions of the law applicable to foods, as reported in F. N. J. 3644.

Lash's Bitters—Lash, Inc., Anaheim, Calif. Shipped Oct. 27, 1941. Composition essentially a water alcohol extract of laxative plant drugs such as cascara sagrada and senna. Misbranded because of false and misleading label representations that it was a regulator, an adequate remedy for indigestion, headaches, and loss of appetite arising from imperfect digestion, and a proper treatment for chronic constipation, and that it would not cause the harsh after effects which may accompany cathartics nor would its continued use be likely to result in a dependence on laxatives to move the bowels—[D. D. N. J., F. D. C. 689, February 1943].

Renal Pomade—Frederick Godfrey, trading as Adams Products Company, Adams, N. Y. Shipped May 14, 1940. Composition an amber colored ointment containing betanaphthol and volatile oils with cedar like odor, incorporated in a base consisting chiefly of petrolatum and a smaller amount of fatty material. Misbranded because label represented that when used alone or in conjunction with certain pulling, massaging and kneading treatments, preparation would produce beneficial effects in treatment of baldness and falling hair, whereas government charged it would not—[D. D. N. J., F. D. C. 731, April 1943].

Savol and Savol Cream—Savol Chemical Company, Mercer, Pa. Shipped between June 23 and August 13, 1941. Composition Savol essentially cresols, alkali soaps and water, Savol Cream, essentially zinc oxide, barium sulfate, petrolatum and perfume materials. The first named was misbranded because of false and misleading label representations that it would be effective in protecting against and preventing serious infection and treating bites of animals, open sores, irritation of throat or nasal passages arising from catarrh, hay fever or kindred ailments, would minimize the possibility of infected sores, abscesses, boils, felonies and all complications due to infections, and always be helpful and often curative. Savol Cream was misbranded because of false and misleading label representations that it was an antiseptic and would be efficacious in treating cuts, boils, felonies, sores, ulcers, itching, and all forms of rashes, eczema, skin disorders in general and bites of animals and also when used on the neck in cases of sore throat, croup and enlarged glands. Both products further misbranded in that labels failed to give common or usual names of active ingredients, or an accurate statement of the quantity of contents—[D. D. N. J., F. D. C. 687, February 1943].

Todd's Capsules—J. E. Todd, Inc., Kenmore, N. Y. Shipped August 16 and Nov. 21, 1941. Composition in each capsule magnesium oxide (approximately 0.16 grain), calcium carbonate (about 2 grains), sodium bicarbonate (from 2.1 to 3.8 grains), a gum resin such as olibanum, small amounts of an iron compound and sulfur, and sand varying from 2.5 to 4.3 grains per capsule. Misbranded because label falsely and misleadingly represented that the product would relieve conditions of excess acidity and in that way gradually alleviate aches and pains that may be symptoms of, or associated with, "rheumatic conditions"—[D. D. N. J., F. D. C. 690, February 1943].

Tu-Way Massagers—E. W. Arnold Company, Logansport, Ind. Shipped Aug. 21, 1941. A massaging device which "consisted of a series of rubber covered disks, attached to a handle, which were to be rolled over portions of the body." Misbranded because of false and misleading representations in accompanying circular that it was founded on an exact scientific principle and would positively remove the fat spots, beautify the figure and break down fatty deposits so that they would be oxidized within the body, with the result that the residue would be carried away by the blood stream and disappear through the organs of elimination leaving the flesh firmer and more solid, that it would be wonderfully soothing and strengthening to tired, aching neck and shoulders, that it would be effective in correcting fleshy, corpulent and pendulous abdomens, and stimulate activity of the liver—[D. D. N. J., F. D. C. 692, February 1943].

Ultrazol—Post Institute Sales Corporation, Newburgh, N. Y. Shipped Sept. 30, 1941. Composition Ultrazol Fluid, essentially light mineral oil, oxyquinoline (0.12 Gm. per 100 cubic centimeters), organic substances including cholesterol, and perfume, Ultrazol Hair Bath, essentially a wetting agent, such as sodium lauryl sulfate, a small amount of cholesterol and other organic material. Ultrazol Fluid misbranded because of false and misleading representations on cartons and labels and in accompanying leaflets that this combination would promote luxuriant hair and scalp hygiene, remove dandruff, help check excessive hair loss, and combat premature graying, that it would bring about a condition under which the natural hair growing process would be unimpeded and natural hair growth would become possible, that it would remove obstruction to the development of fuzz or thim, short hair, stop abnormal hair loss and make dull, dry, faded hair become brilliant, that new hair would be produced on gray heads, which frequently would be of the original shade, thus indicating that it would prevent graying, that it would strengthen the hair for lasting, artistic permanent waving, give dyed hair an even, "refined" luster, and normalize dry or oily scalp—[D. D. N. J., F. D. C. 693, February 1943].

Correspondence

"MILK BORNE IMMUNITY"

To the Editor:—The editorial entitled "Milk Borne Immunity" which appeared in the February 19 issue of THE JOURNAL calls attention to the work of Berry and Slavin on the transfer to young mice of specific antibodies contained in the breast milk of herpes virus immune mothers and concludes that the "extension of the theory of milk borne immunity to include certain virus diseases has important clinical applications." Evidence for the existence of milk borne immunity in rabbit pox, a virus disease of rabbits, was presented in earlier reports which escaped the attention of both your editorialist and of the investigators cited.

Three epidemics of rabbit pox occurred in a large breeding colony between the spring of 1930 and the winter of 1933. The first and third epidemics were relatively mild, but the second epidemic occurred with explosive violence in a highly malignant form. Investigation through clinical, pathologic, immunologic and host-range experiments identified the etiologic agent as a filtrable virus, qualitatively related to vaccine virus but more virulent. "None of the nursing young of four mothers immune to the causative agent of the second epidemic contracted the disease during the third epidemic. On the other hand, the infection was noted in all of the young of a susceptible doe, and also in every member of a litter of nursing age which had been weaned prematurely by their immune mother because of the mother's physical deterioration. This evidence indicates that nursing a specifically immune mother probably protects young animals from developing the lesions of a spontaneous and epidemic disease, rabbit pox. . . . the protective influence derived from nursing an immune mother, unlike the specific immunity acquired by recovery from actual infection, was of comparatively short duration" (Rosahn, P. D., and Hu, C. K.: Rabbit Pox: Report of an Epidemic, *J. Exper. Med.* 62:331 [Sept.] 1935). The loss of immunity noted in rabbit pox parallels the later findings of Berry and Slavin with regard to herpes infection of mice.

Following the potential exposure of our breeding stock to a case of rabbit pox, 1,185 young animals were vaccinated with vaccine virus as a prophylactic measure. "Under the wholly dependent conditions of nursing there was a striking tendency toward the maintenance of a refractory state. It was found that an immune mother conveyed to the litter some measure of protection against the manifestations of vaccinia. The effect of this passive immunity was shown not only with regard to the character of the local reaction but also in the lower incidence and delayed time of development of generalized manifestations" (Pearce, Louise; Hu, C. K., and Rosahn, P. D.: The Reaction of the Nursing Rabbit to Vaccination with Vaccine Virus, *J. Immunol.* 31:73 [Aug.] 1936). Coincident with the observations on these vaccinated young, observations were conducted also on the unvaccinated members, chiefly nurslings, of the breeding colony. Here again the conclusion was reached that "an immune nursing doe conveyed to the litter some protection against the effects of vaccinia" (Pearce, Louise; Rosahn, P. D., and Hu, C. K.: Epidemiological Aspects of Spontaneously Acquired Vaccinia in the Rabbit, *J. Path. & Bact.* 43:299 [Sept.] 1936).

The reports cited indicate that a milk borne immunity occurs in rabbits exposed to pox and vaccinia, virus diseases which are qualitatively related. This evidence, together with the subsequent findings of Berry and Slavin with respect to herpes infection of mice, suggests that milk borne immunity is a biologic phenomenon not limited to a particular virus or species.

PAUL D. ROSAHN, M.D., New Britain, Conn.

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, March 18, page 795.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Part I-II. Various centers, May 1-3. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Written. Various large cities, May 8. Oral. Chicago, June 9-10. Final date for filing application is April 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written. Various centers Oct. 16. Candidates in military service may take examination at their place of duty. Final date for filing application is August 15. Asst. Sec., Dr. W. A. Werrell, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS & GYNECOLOGY. Oral. Part II. Pittsburgh, June 7-13. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: New York, June 2-5. Chicago, Oct. 5-7. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Oral and Written. Part I. Chicago, New Orleans, New York and San Francisco, October. Final date for filing application is August 1. Sec., Dr. G. A. Caldwell, 3503 Prytania St., New Orleans.

AMERICAN BOARD OF OTOLARYNGOLOGY: Oral. New York City, June 1-4. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City, Ia.

AMERICAN BOARD OF PATHOLOGY: Oral and Written. Chicago, June 7-8. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: Written. Locally, Sept. 22. Oral. St. Louis, Nov. 8 or 9. Final date for filing application is July 8. Sec., Dr. C. A. Aldrich, 115½ First Ave. S.W., Rochester, Minn.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Societies: Right of Individual Member to Restrain Society from Admitting an Applicant Irregularly.

—Walker, a member in good standing of the Medical Society of Mobile County, Ala., a "voluntary nonprofit" corporation, filed a bill to restrain the society and its secretary, Scales, from recognizing or seating Webb and Greene as members of the society until they had been duly elected as members in the manner provided in the society's constitution. The society's constitution, the bill alleged, provided that three adverse votes should reject any applicant for membership and that when the applications of both Webb and Greene were considered by the society membership more than three adverse votes were cast against their admittance but that nevertheless the secretary of the society had enrolled Webb and Greene as members of the society or that he intended so to do, and that the society intended to recognize them as members. The society and Scales demurred to the bill, and when the demurrers were overruled they appealed to the Supreme Court of Alabama.

Membership in a voluntary association, said the Supreme Court, is a privilege which may be accorded or withheld by the association, and not a right which can be gained independently and then enforced. The courts cannot compel the admission of an individual into such an association, and if his application is refused he is entirely without legal remedy, no matter how arbitrary or unjust be his exclusion. Medical societies have the right to make their own rules on the subject of admission or exclusion of members, and these rules are considered as articles of agreement, to which all who are members become parties. 4 Amer. Jur. 462, *Chapman v.*

American Legion, 14 So. (2d) 225, 147 A. L. R. 585 and Note. They may make their own constitution and by-laws; and, so long as they remain unchanged, each member is alike bound and shielded by them. The society too must observe its own constitution and by-laws until it changes them in legal form. Of course, such constitution and by-laws, to be obligatory, must not contravene public law nor any principle of public policy. *Weatherly v. Medical & Surgical Society of Montgomery County*, 76 Ala. 567. We know of no case, continued the court, in which injunctive relief has been sought to prevent a medical society from violating the express provisions of its own constitution in respect to the selection of its members. But that such relief is available is clearly indicated in the *Weatherly* case, *supra*, where the court said:

The society, too, must observe its own constitution and laws, until it changes them in legal form.

Mandamus is a proper remedy to correct the wrong of illegal expulsion from the society, illegal because done in violation of the constitution, by-laws, rules and regulations of the society. We can see no reason for withholding injunctive relief against the anticipated violation of the constitution in the present case. In the one case the illegal act has been accomplished and mandamus is the proper remedy to undo the wrong. In the other, the illegal act is only threatened and mandamus will not lie.

Ordinarily, said the court, a court of equity will not interfere with the internal affairs of a voluntary association or assume jurisdiction to restrain its acts done or attempted in accordance with its rules and within the scope of its powers. On the other hand, if the act complained of is unauthorized or unlawful and occasions irreparable injury to the complainant member for which there is no adequate and complete remedy at law, equitable relief by way of injunction will be granted. Here it is earnestly insisted that irreparable injury to the complainant, Walker, is not shown. It is perfectly clear, the court answered,

that the threatened acts of the society and its secretary are unauthorized, unlawful and in direct violation of the society's constitution. As previously pointed out, this court has ruled to the effect that Walker's membership in the medical society here involved is a property right of value; that the constitution of the society is a contract between its members and one that the society itself must observe until changed in legal form. A court of equity will endeavor to the extent of its powers to bind men's consciences so far as they can be bound to a true and literal performance of their agreements and will not suffer them to depart from their contracts at pleasure, leaving the party with whom they have contracted to the mere chance of any damage that a jury may assess. The matter is discretionary with the courts, and the courts regard it as unwise, even if it were possible, to promulgate or declare unchangeable rules to govern all cases. The matter must depend to a large extent on the facts and circumstances of each case. As ordinarily understood, an injury is irreparable, within the law of injunctions, where it is of such a character that a fair and reasonable redress may not be had in a court of law, so that to refuse the injunction would be a denial of justice. In respect to its membership, the proposed procedure on the part of the society and its secretary amounts to a complete destruction of the constitution of the society and opens the door to the destruction of Walker's, or any other member's, every right in it. In our opinion there is no adequate remedy at law, and under the allegations of the bill filed by Walker injunctive relief should be granted.

It was next insisted that Walker must first exhaust all remedies provided in the society before he could appeal to the courts for relief. The action complained of, the court answered, shows a threatened violation of the constitution of the society, in consequence of which there can be no redress except by resort to legal remedies. Where the threatened procedure is irregular and without jurisdiction, the member aggrieved thereby may seek judicial redress by a direct appeal to the courts in the first instance. 7 Corpus Juris Secundum, pages 81, 82.

However, because neither Drs. Webb nor Greene, the applicants who it is alleged were about to be illegally admitted to

the society, were made parties to the action, the majority of the court held that the demurrers interposed by the society and its secretary should have been sustained, since "the court [should] not interfere in a case involving in a collateral manner the right of parties who have no opportunity of defending their interest." The judgment of the lower court overruling the demurrers was accordingly reversed and the cause was remanded. *Medical Society of Mobile County v. Walker*, 16 So. (2d) 321 (Ala., 1944).

- Arizona State Medical Association, Phoenix, April 14-15. Dr. Frank J. Milloy, 112 N. Central Ave., Phoenix, Secretary.
- Arkansas Medical Society, Little Rock, April 17-18. Dr. W. R. Brooksher, 602 Garrison Avenue, Fort Smith, Secretary.
- Association of American Physicians, Atlantic City, May 9. Dr. Joseph T. Wearn, Lakeside Hospital, Cleveland, Secretary.
- California Medical Association, Los Angeles, May 7-8. Dr. George H. Kress, 450 Sutter Street, San Francisco 8, Secretary.
- Connecticut State Medical Society, Bridgeport, May 2-4. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.
- Florida Medical Association, St. Petersburg, April 13-14. Dr. Shaler Richardson, 111 West Adams St., Jacksonville, Secretary.
- Georgia, Medical Association of, Savannah, May 9-12. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta, Secretary.
- Illinois State Medical Society, Chicago, May 16-18. Dr. Harold M. Camp, 224 S. Main St., Monmouth, Secretary.
- Iowa State Medical Society, Des Moines, April 20-21. Dr. Robert L. Parker, 3510 Sixth Avenue, Des Moines, Secretary.
- Kansas Medical Society, Topeka, May 10-11. Dr. F. R. Croson, 112 West Sixth Street, Topeka, Secretary.
- Louisiana State Medical Society, New Orleans, April 24-26. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, 13, Secretary.
- Maryland, Medical and Chirurgical Faculty of, Baltimore, April 25-26. Dr. W. Houston Toulson, 1211 Cathedral St., Baltimore, Secretary.
- Minnesota State Medical Association, Rochester, April 13-15. Dr. B. B. Souster, 493 Lowry Medical Arts Bldg., St. Paul, Secretary.
- Mississippi State Medical Association, Jackson, May 9-10. Dr. T. M. Dye, Box 295, Clarksdale, Secretary.
- Missouri State Medical Association, Kansas City, April 23-25. Dr. Ralph L. Thompson, 634 N. Grand Blvd., St. Louis, Executive Secretary.
- National Tuberculosis Association, Chicago, May 10-12. Dr. Charles J. Hatfield, 1790 Broadway, New York, Secretary.
- Nebraska State Medical Association, Omaha, May 1-4. Dr. R. B. Adams, 416 Federal Securities Bldg., Lincoln, Secretary.
- New Hampshire Medical Society, Manchester, May 16. Dr. C. R. Metcalf, 5 S. State St., Concord, Secretary.
- New Jersey, Medical Society of, Atlantic City, April 25-27. Dr. Alfred Stahl, 55 Lincoln Park, Newark, Secretary.
- New York, Medical Society of the State of, New York, May 8-11. Dr. Peter Irving, 292 Madison Ave., New York 17, Secretary.
- North Carolina, Medical Society of the State of, May 1-3. Dr. R. D. McMillan, P. O. Box 232, Red Springs, Secretary.
- North Dakota State Medical Association, Fargo, May 7-9. Dr. L. W. Larson, 221 5th Street, Bismarck, Secretary.
- Northern Tri-State Medical Association, Toledo, Ohio, April 11. Dr. Oscar P. Klotz, 127 W. Hardin St., Findlay, Ohio, Secretary.
- Ohio State Medical Association, Columbus, May 2-4. Mr. Charles S. Nelson, 79 E. State St., Columbus, Executive Secretary.
- Oklahoma State Medical Association, Tulsa, April 24-26. Dr. L. J. Moorman, 1200 N. Walker St., Oklahoma City, Secretary.
- Society of American Bacteriologists, New York, May 3-5. Dr. W. C. Frazier, 310 Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Tennessee State Medical Association, Nashville, April 11-13. Dr. H. H. Shoulders, 706 Church St., Nashville, Secretary.
- Texas, State Medical Association of, Dallas, May 10-11. Dr. Holman Taylor, 1404 W. El Paso Street, Fort Worth, Secretary.
- West Virginia Medical Association, Wheeling, May 15-16. Mr. Charles Lively, P. O. Box 1031, Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia 207:1-140 (Jan.) 1944

- Nature of Graves' Disease, with Special Reference to Its Ophthalmic Component J. H. Means—p. 1
- *Treatment of Addison's Disease with Pellets of Desoxycorticosterone Acetate R. A. Shipley—p. 19
- Use of Fibrinogen in Rapid Method of Determining Cell Volume S. Gray—p. 29
- *Inhalatory Route for Prophylaxis and Treatment of Experimental Influenza: I. Distribution of Inhaled Material A. P. Krueger and others—p. 40
- Yeast-like Fungi in Intestinal Tract of Chronically Institutionalized Patients. O. Felsenfeld—p. 60.
- Treatment of 134 Cases of Meningococcal Infection with Massive Doses of Sulfadiazine B. A. Marangoni and V. C. D'Agati—p. 67.
- Idiopathic Hypoproteinemia F. D. Murphy and J. K. Clark—p. 77.

Pellets of Desoxycorticosterone Acetate in Addison's Disease.—Shipley reports observations on 7 patients with Addison's disease treated with pellets of desoxycorticosterone acetate. The pellets were inserted in the infrascapular region through an incision about 1 cm. long. Pockets radiating in various directions were made with a hemostat beneath the skin in the subcutaneous tissue. As many as 6 pellets could easily be inserted through one incision. There were no infections and in no cases were pellets spontaneously extruded. When the old pellets had been in place long enough to undergo considerable absorption, they were removed and weighed, and new pellets were inserted. Five of the 7 patients with Addison's disease were maintained well by this method for seven to forty months and were able to carry on work involving moderate physical activity. The other 2 patients were not satisfactorily controlled either by the pellets or by the compound administered by injection. Both of these patients died from disease. One patient died suddenly after an attack of appendicitis at a time when he seemed to be convalescing satisfactorily. Patients under therapy with pellets of desoxycorticosterone acetate may easily become hypoglycemic by fasting. They are particularly vulnerable in the presence of an infection. Pellet therapy with desoxycorticosterone acetate is highly useful for the maintenance of most patients with Addison's disease. During infections or other conditions imposing stress the requirement for hormone is increased and under these circumstances additional therapy, chiefly in the form of cortical extract, should be given. The effective life of the 75 mg. pellet, which is being used at the present, is approximately nine to ten months, the average daily absorption is 0.21 mg. per pellet, and the average number of pellets required is four to six. The rate of absorption is reasonably constant. It has been possible to implant pellets without subjecting patients to a lengthy preliminary period of therapy with injections.

Inhalatory Route for Prophylaxis and Treatment of Influenza.—The work of Smorodintsev and other Russian investigators on the prevention and treatment of human influenza by inhalation of immune horse serum stimulated Krueger and his associates to investigate this possibility. They describe an atomizer capable of producing a fine particle mist, preparation of horse immune plasma and its globulin fraction and its employment in experiments on mice. Immunization was also attempted with a neutral mixture of serum and active virus. High titer horse immune serum, or its globulin fraction administered by intranasal inoculation or by inhalation protected mice against subsequent intranasal infection with influenza virus. The degree of protection conferred increased with the time of exposure to the globulin spray. Whole immune plasma was superior to any individual globulin fraction in the degree and

duration of its protective power for mice. Treatment of mice with horse immune serum intranasally, or globulin by inhalation, was effective in reducing the lung lesions. Early treatment is important. The value of repeated treatments in lessening the severity of the experimental disease was definitely established, the lung lesions decreasing as the number of treatments is increased. Neutral mixtures of immune serum and active virus were ineffective in producing an active immunity in mice. Mice subjected to repeated intranasal inoculations of a virus treated with formaldehyde showed a considerable degree of immunity when tested ten days after the last inoculation. Immunity failed to develop in mice receiving concurrent intranasal serum treatments along with the formaldehyde treated virus.
